C History and License 77
This document describes the Python Distribution Utilities ("Distutils") from the module developer’s point of view, describing how to use the Distutils to make Python modules and extensions easily available to a wider audience with very little overhead for build/release/install mechanics.
CHAPTER ONE

AN INTRODUCTION TO DISTUTILS

This document covers using the Distutils to distribute your Python modules, concentrating on the role of developer/distributor: if you’re looking for information on installing Python modules, you should refer to the install-index chapter.

1.1 Concepts & Terminology

Using the Distutils is quite simple, both for module developers and for users/administrators installing third-party modules. As a developer, your responsibilities (apart from writing solid, well-documented and well-tested code, of course!) are:

• write a setup script (setup.py by convention)
• (optional) write a setup configuration file
• create a source distribution
• (optional) create one or more built (binary) distributions

Each of these tasks is covered in this document.

Not all module developers have access to a multitude of platforms, so it’s not always feasible to expect them to create a multitude of built distributions. It is hoped that a class of intermediaries, called packagers, will arise to address this need. Packagers will take source distributions released by module developers, build them on one or more platforms, and release the resulting built distributions. Thus, users on the most popular platforms will be able to install most popular Python module distributions in the most natural way for their platform, without having to run a single setup script or compile a line of code.

1.2 A Simple Example

The setup script is usually quite simple, although since it’s written in Python, there are no arbitrary limits to what you can do with it, though you should be careful about putting arbitrarily expensive operations in your setup script. Unlike, say, Autoconf-style configure scripts, the setup script may be run multiple times in the course of building and installing your module distribution.

If all you want to do is distribute a module called foo, contained in a file foo.py, then your setup script can be as simple as this:

    from distutils.core import setup
    setup(name='foo',
          version='1.0',
          py_modules=['foo'],
    )

Some observations:
• most information that you supply to the Distutils is supplied as keyword arguments to the `setup()` function

• those keyword arguments fall into two categories: package metadata (name, version number) and information about what’s in the package (a list of pure Python modules, in this case)

• modules are specified by module name, not filename (the same will hold true for packages and extensions)

• it’s recommended that you supply a little more metadata, in particular your name, email address and a URL for the project (see section Writing the Setup Script for an example)

To create a source distribution for this module, you would create a setup script, `setup.py`, containing the above code, and run this command from a terminal:

```bash
python setup.py sdist
```

For Windows, open a command prompt window (`Start → Accessories`) and change the command to:

```bash
setup.py sdist
```

`sdist` will create an archive file (e.g., tarball on Unix, ZIP file on Windows) containing your setup script `setup.py`, and your module `foo.py`. The archive file will be named `foo-1.0.tar.gz` (or `.zip`), and will unpack into a directory `foo-1.0`.

If an end-user wishes to install your `foo` module, all she has to do is download `foo-1.0.tar.gz` (or `.zip`), unpack it, and—from the `foo-1.0` directory—run

```bash
python setup.py install
```

which will ultimately copy `foo.py` to the appropriate directory for third-party modules in their Python installation.

This simple example demonstrates some fundamental concepts of the Distutils. First, both developers and installers have the same basic user interface, i.e. the setup script. The difference is which Distutils commands they use: the `sdist` command is almost exclusively for module developers, while `install` is more often for installers (although most developers will want to install their own code occasionally).

If you want to make things really easy for your users, you can create one or more built distributions for them. For instance, if you are running on a Windows machine, and want to make things easy for other Windows users, you can create an executable installer (the most appropriate type of built distribution for this platform) with the `bdist_wininst` command. For example:

```bash
python setup.py bdist_wininst
```

will create an executable installer, `foo-1.0.win32.exe`, in the current directory.

Other useful built distribution formats are RPM, implemented by the `bdist_rpm` command, Solaris `pkgtool` (`bdist_pkgtool`), and HP-UX `swinstall` (`bdist_sdux`). For example, the following command will create an RPM file called `foo-1.0.noarch.rpm`:

```bash
python setup.py bdist_rpm
```

(The `bdist_rpm` command uses the `rpm` executable, therefore this has to be run on an RPM-based system such as Red Hat Linux, SuSE Linux, or Mandrake Linux.)

You can find out what distribution formats are available at any time by running

```bash
python setup.py bdist --help-formats
```

### 1.3 General Python terminology

If you’re reading this document, you probably have a good idea of what modules, extensions, and so forth are. Nevertheless, just to be sure that everyone is operating from a common starting point, we offer the following glossary of common Python terms:

- **module** the basic unit of code reusability in Python: a block of code imported by some other code. Three types of modules concern us here: pure Python modules, extension modules, and packages.
**pure Python module** a module written in Python and contained in a single .py file (and possibly associated .pyc and/or .pyo files). Sometimes referred to as a “pure module.”

**extension module** a module written in the low-level language of the Python implementation: C/C++ for Python, Java for Jython. Typically contained in a single dynamically loadable pre-compiled file, e.g. a shared object (.so) file for Python extensions on Unix, a DLL (given the .pyd extension) for Python extensions on Windows, or a Java class file for Jython extensions. (Note that currently, the Distutils only handles C/C++ extensions for Python.)

**package** a module that contains other modules; typically contained in a directory in the filesystem and distinguished from other directories by the presence of a file __init__.py.

**root package** the root of the hierarchy of packages. (This isn’t really a package, since it doesn’t have an __init__.py file. But we have to call it something.) The vast majority of the standard library is in the root package, as are many small, standalone third-party modules that don’t belong to a larger module collection. Unlike regular packages, modules in the root package can be found in many directories: in fact, every directory listed in sys.path contributes modules to the root package.

## 1.4 Distutils-specific terminology

The following terms apply more specifically to the domain of distributing Python modules using the Distutils:

**module distribution** a collection of Python modules distributed together as a single downloadable resource and meant to be installed en masse. Examples of some well-known module distributions are NumPy, SciPy, PIL (the Python Imaging Library), or mxBase. (This would be called a package, except that term is already taken in the Python context: a single module distribution may contain zero, one, or many Python packages.)

**pure module distribution** a module distribution that contains only pure Python modules and packages. Sometimes referred to as a “pure distribution.”

**non-pure module distribution** a module distribution that contains at least one extension module. Sometimes referred to as a “non-pure distribution.”

**distribution root** the top-level directory of your source tree (or source distribution); the directory where setup.py exists. Generally setup.py will be run from this directory.
WRITING THE SETUP SCRIPT

The setup script is the centre of all activity in building, distributing, and installing modules using the Distutils. The main purpose of the setup script is to describe your module distribution to the Distutils, so that the various commands that operate on your modules do the right thing. As we saw in section A Simple Example above, the setup script consists mainly of a call to setup(), and most information supplied to the Distutils by the module developer is supplied as keyword arguments to setup().

Here’s a slightly more involved example, which we’ll follow for the next couple of sections: the Distutils’ own setup script. (Keep in mind that although the Distutils are included with Python 1.6 and later, they also have an independent existence so that Python 1.5.2 users can use them to install other module distributions. The Distutils’ own setup script, shown here, is used to install the package into Python 1.5.2.)

#!/usr/bin/env python

from distutils.core import setup

setup(name='Distutils',
      version='1.0',
      description='Python Distribution Utilities',
      author='Greg Ward',
      author_email='gward@python.net',
      url='http://www.python.org/sigs/distutils-sig/',
      packages=['distutils', 'distutils.command'],
)

There are only two differences between this and the trivial one-file distribution presented in section A Simple Example: more metadata, and the specification of pure Python modules by package, rather than by module. This is important since the Distutils consist of a couple of dozen modules split into (so far) two packages; an explicit list of every module would be tedious to generate and difficult to maintain. For more information on the additional meta-data, see section Additional meta-data.

Note that any pathnames (files or directories) supplied in the setup script should be written using the Unix convention, i.e. slash-separated. The Distutils will take care of converting this platform-neutral representation into whatever is appropriate on your current platform before actually using the pathname. This makes your setup script portable across operating systems, which of course is one of the major goals of the Distutils. In this spirit, all pathnames in this document are slash-separated.

This, of course, only applies to pathnames given to Distutils functions. If you, for example, use standard Python functions such as glob.glob() or os.listdir() to specify files, you should be careful to write portable code instead of hardcoding path separators:

glob.glob(os.path.join('mydir', 'subdir', '*.html'))

os.listdir(os.path.join('mydir', 'subdir'))
2.1 Listing whole packages

The `packages` option tells the Distutils to process (build, distribute, install, etc.) all pure Python modules found in each package mentioned in the `packages` list. In order to do this, of course, there has to be a correspondence between package names and directories in the filesystem. The default correspondence is the most obvious one, i.e. package `distutils` is found in the directory `distutils` relative to the distribution root. Thus, when you say `packages = ['foo']` in your setup script, you are promising that the Distutils will find a file `foo/__init__.py` (which might be spelled differently on your system, but you get the idea) relative to the directory where your setup script lives. If you break this promise, the Distutils will issue a warning but still process the broken package anyway.

If you use a different convention to lay out your source directory, that’s no problem: you just have to supply the `package_dir` option to tell the Distutils about your convention. For example, say you keep all Python source under `lib`, so that modules in the “root package” (i.e., not in any package at all) are in `lib`, modules in the `foo` package are in `lib/foo`, and so forth. Then you would put

```python
package_dir = {'': 'lib'}
```

in your setup script. The keys to this dictionary are package names, and an empty package name stands for the root package. The values are directory names relative to your distribution root. In this case, when you say `packages = ['foo']`, you are promising that the file `lib/foo/__init__.py` exists.

Another possible convention is to put the `foo` package right in `lib`, the `foo.bar` package in `lib/bar`, etc. This would be written in the setup script as

```python
package_dir = {'foo': 'lib'}
```

A package: dir entry in the `package_dir` dictionary implicitly applies to all packages below package, so the `foo.bar` case is automatically handled here. In this example, having `packages = ['foo', 'foo.bar']` tells the Distutils to look for `lib/__init__.py` and `lib/bar/__init__.py`. (Keep in mind that although `package_dir` applies recursively, you must explicitly list all packages in `packages`: the Distutils will not recursively scan your source tree looking for any directory with an `__init__.py` file.)

2.2 Listing individual modules

For a small module distribution, you might prefer to list all modules rather than listing packages—especially the case of a single module that goes in the “root package” (i.e., no package at all). This simplest case was shown in section A Simple Example; here is a slightly more involved example:

```python
py_modules = ['mod1', 'pkg.mod2']
```

This describes two modules, one of them in the “root” package, the other in the `pkg` package. Again, the default package/directory layout implies that these two modules can be found in `mod1.py` and `pkg/mod2.py`, and that `pkg/__init__.py` exists as well. And again, you can override the package/directory correspondence using the `package_dir` option.

2.3 Describing extension modules

Just as writing Python extension modules is a bit more complicated than writing pure Python modules, describing them to the Distutils is a bit more complicated. Unlike pure modules, it’s not enough just to list modules or packages and expect the Distutils to go out and find the right files; you have to specify the extension name, source file(s), and any compile/link requirements (include directories, libraries to link with, etc.).

All of this is done through another keyword argument to `setup()`, the `ext_modules` option. `ext_modules` is just a list of `Extension` instances, each of which describes a single extension module. Suppose your distribution includes a single extension, called `foo` and implemented by `foo.c`. If no additional instructions to the compiler/linker are needed, describing this extension is quite simple:

```python
Extension('foo', ['foo.c'])
```
The `Extension` class can be imported from `distutils.core` along with `setup()`. Thus, the setup script for a module distribution that contains only this one extension and nothing else might be:

```python
from distutils.core import setup, Extension
setup(name='foo',
      version='1.0',
      ext_modules=[Extension('foo', ['foo.c'])],
)
```

The `Extension` class (actually, the underlying extension-building machinery implemented by the `build_ext` command) supports a great deal of flexibility in describing Python extensions, which is explained in the following sections.

### 2.3.1 Extension names and packages

The first argument to the `Extension` constructor is always the name of the extension, including any package names. For example,

```python
Extension('foo', ['src/foo1.c', 'src/foo2.c'])
```

describes an extension that lives in the root package, while

```python
Extension('pkg.foo', ['src/foo1.c', 'src/foo2.c'])
```

describes the same extension in the `pkg` package. The source files and resulting object code are identical in both cases; the only difference is where in the filesystem (and therefore where in Python's namespace hierarchy) the resulting extension lives.

If you have a number of extensions all in the same package (or all under the same base package), use the `ext_package` keyword argument to `setup()`. For example,

```python
setup(...,
      ext_package='pkg',
      ext_modules=[Extension('foo', ['foo.c']),
                   Extension('subpkg.bar', ['bar.c'])],
)
```

will compile `foo.c` to the extension `pkg.foo`, and `bar.c` to `pkg.subpkg.bar`.

### 2.3.2 Extension source files

The second argument to the `Extension` constructor is a list of source files. Since the Distutils currently only support C, C++, and Objective-C extensions, these are normally C/C++/Objective-C source files. (Be sure to use appropriate extensions to distinguish C++ source files: `.cc` and `.cpp` seem to be recognized by both Unix and Windows compilers.)

However, you can also include SWIG interface (.i) files in the list: the `build_ext` command knows how to deal with SWIG extensions: it will run SWIG on the interface file and compile the resulting C/C++ file into your extension.

This warning notwithstanding, options to SWIG can be currently passed like this:

```python
setup(...,
      ext_modules=[Extension('_foo', ['foo.i'],
                              swig_opts=['-modern', '-I../include'])],
      py_modules=['foo'],
)
```

Or on the commandline like this:

```bash
> python setup.py build_ext --swig-opts="-modern -I../include"
```

2.3. Describing extension modules
On some platforms, you can include non-source files that are processed by the compiler and included in your extension. Currently, this just means Windows message text (.mc) files and resource definition (.rc) files for Visual C++. These will be compiled to binary resource (.res) files and linked into the executable.

2.3.3 Preprocessor options

Three optional arguments to `Extension` will help if you need to specify include directories to search or preprocessor macros to define/undefine: `include_dirs`, `define_macros`, and `undef_macros`.

For example, if your extension requires header files in the `include` directory under your distribution root, use the `include_dirs` option:

```python
Extension('foo', ['foo.c'], include_dirs=['include'])
```

You can specify absolute directories there; if you know that your extension will only be built on Unix systems with X11R6 installed to `/usr`, you can get away with:

```python
Extension('foo', ['foo.c'], include_dirs=['/usr/include/X11'])
```

You should avoid this sort of non-portable usage if you plan to distribute your code: it’s probably better to write C code like:

```
#include <X11/Xlib.h>
```

If you need to include header files from some other Python extension, you can take advantage of the fact that header files are installed in a consistent way by the Distutils `install_headers` command. For example, the Numerical Python header files are installed (on a standard Unix installation) to `/usr/local/include/python1.5/Numerical`. (The exact location will differ according to your platform and Python installation.) Since the Python include directory—`/usr/local/include/python1.5` in this case—is always included in the search path when building Python extensions, the best approach is to write C code like:

```
#include <Numerical/arrayobject.h>
```

If you must put the Numerical include directory right into your header search path, though, you can find that directory using the Distutils `distutils.sysconfig` module:

```python
from distutils.sysconfig import get_python_inc

incdir = os.path.join(get_python_inc(plat_specific=1), 'Numerical')

setup(...,
      Extension(..., include_dirs=[incdir]),
    )
```

Even though this is quite portable—it will work on any Python installation, regardless of platform—it’s probably easier to just write your C code in the sensible way.

You can define and undefine pre-processor macros with the `define_macros` and `undef_macros` options. `define_macros` takes a list of `(name, value)` tuples, where `name` is the name of the macro to define (a string) and `value` is its value: either a string or None. (Defining a macro FOO to None is the equivalent of a bare `#define FOO` in your C source: with most compilers, this sets FOO to the string 1.) `undef_macros` is just a list of macros to undefine.

For example:

```python
Extension(...,
    define_macros=[('NDEBUG', '1'),
                  ('HAVE_STRTIME', None)],
    undef_macros=['HAVE_FOO', 'HAVE_BAR'])
```

is the equivalent of having this at the top of every C source file:

```
#define NDEBUG 1
#define HAVE_STRTIME
#undef HAVE_FOO
#undef HAVE_BAR
```
2.3.4 Library options

You can also specify the libraries to link against when building your extension, and the directories to search for those libraries. The libraries option is a list of libraries to link against, library_dirs is a list of directories to search for libraries at link-time, and runtime_library_dirs is a list of directories to search for shared (dynamically loaded) libraries at run-time.

For example, if you need to link against libraries known to be in the standard library search path on target systems

```python
Extension(...,
    libraries=['gdbm', 'readline'])
```

If you need to link with libraries in a non-standard location, you’ll have to include the location in library_dirs:

```python
Extension(...,
    library_dirs=['/usr/X11R6/lib'],
    libraries=['X11', 'Xt'])
```

(Again, this sort of non-portable construct should be avoided if you intend to distribute your code.)

2.3.5 Other options

There are still some other options which can be used to handle special cases.

The optional option is a boolean; if it is true, a build failure in the extension will not abort the build process, but instead simply not install the failing extension.

The extra_objects option is a list of object files to be passed to the linker. These files must not have extensions, as the default extension for the compiler is used.

extra_compile_args and extra_link_args can be used to specify additional command line options for the respective compiler and linker command lines.

export_symbols is only useful on Windows. It can contain a list of symbols (functions or variables) to be exported. This option is not needed when building compiled extensions: Distutils will automatically add initmodule to the list of exported symbols.

The depends option is a list of files that the extension depends on (for example header files). The build command will call the compiler on the sources to rebuild extension if any on this files has been modified since the previous build.

2.4 Relationships between Distributions and Packages

A distribution may relate to packages in three specific ways:

1. It can require packages or modules.
2. It can provide packages or modules.
3. It can obsolete packages or modules.

These relationships can be specified using keyword arguments to the distutils.core.setup() function.

Dependencies on other Python modules and packages can be specified by supplying the requires keyword argument to setup(). The value must be a list of strings. Each string specifies a package that is required, and optionally what versions are sufficient.

To specify that any version of a module or package is required, the string should consist entirely of the module or package name. Examples include 'mymodule' and 'xml.parsers.expat'.

If specific versions are required, a sequence of qualifiers can be supplied in parentheses. Each qualifier may consist of a comparison operator and a version number. The accepted comparison operators are:
< > ==
<= >= !=

These can be combined by using multiple qualifiers separated by commas (and optional whitespace). In this case, all of the qualifiers must be matched; a logical AND is used to combine the evaluations.

Let’s look at a bunch of examples:

<table>
<thead>
<tr>
<th>Requires Expression</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>==1.0</td>
<td>Only version 1.0 is compatible</td>
</tr>
<tr>
<td>&gt;1.0, !=1.5.1, &lt;2.0</td>
<td>Any version after 1.0 and before 2.0 is compatible, except 1.5.1</td>
</tr>
</tbody>
</table>

Now that we can specify dependencies, we also need to be able to specify what we provide that other distributions can require. This is done using the `provides` keyword argument to `setup()`. The value for this keyword is a list of strings, each of which names a Python module or package, and optionally identifies the version. If the version is not specified, it is assumed to match that of the distribution.

Some examples:

<table>
<thead>
<tr>
<th>Provides Expression</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>mypkg</td>
<td>Provide mypkg, using the distribution version</td>
</tr>
<tr>
<td>mypkg (1.1)</td>
<td>Provide mypkg version 1.1, regardless of the distribution version</td>
</tr>
</tbody>
</table>

A package can declare that it obsoletes other packages using the `obsoletes` keyword argument. The value for this is similar to that of the `requires` keyword: a list of strings giving module or package specifiers. Each specifier consists of a module or package name optionally followed by one or more version qualifiers. Version qualifiers are given in parentheses after the module or package name.

The versions identified by the qualifiers are those that are obsoleted by the distribution being described. If no qualifiers are given, all versions of the named module or package are understood to be obsoleted.

### 2.5 Installing Scripts

So far we have been dealing with pure and non-pure Python modules, which are usually not run by themselves but imported by scripts.

Scripts are files containing Python source code, intended to be started from the command line. Scripts don’t require Distutils to do anything very complicated. The only clever feature is that if the first line of the script starts with `#!` and contains the word “python”, the Distutils will adjust the first line to refer to the current interpreter location. By default, it is replaced with the current interpreter location. The `--executable` (or `-e`) option will allow the interpreter path to be explicitly overridden.

The `scripts` option simply is a list of files to be handled in this way. From the PyXML setup script:

```python
setup(...,
       scripts=['scripts/xmlproc_parse', 'scripts/xmlproc_val'])
```

Changed in version 3.1: All the scripts will also be added to the `MANIFEST` file if no template is provided. See `Specifying the files to distribute`.

### 2.6 Installing Package Data

Often, additional files need to be installed into a package. These files are often data that’s closely related to the package’s implementation, or text files containing documentation that might be of interest to programmers using the package. These files are called package data.

Package data can be added to packages using the `package_data` keyword argument to the `setup()` function. The value must be a mapping from package name to a list of relative path names that should be copied into the package. The paths are interpreted as relative to the directory containing the package (information from the
package_dir mapping is used if appropriate); that is, the files are expected to be part of the package in the source directories. They may contain glob patterns as well.

The path names may contain directory portions; any necessary directories will be created in the installation.

For example, if a package should contain a subdirectory with several data files, the files can be arranged like this in the source tree:

```
setup.py
src/
  mypkg/
    __init__.py
    module.py
    data/
      tables.dat
      spoons.dat
      forks.dat
```

The corresponding call to `setup()` might be:

```
setup(...,
  packages=['mypkg'],
  package_dir={'mypkg': 'src/mypkg'},
  package_data={'mypkg': ['data/*.dat']},
)
```

Changed in version 3.1: All the files that match `package_data` will be added to the MANIFEST file if no template is provided. See `Specifying the files to distribute`.

### 2.7 Installing Additional Files

The `data_files` option can be used to specify additional files needed by the module distribution: configuration files, message catalogs, data files, anything which doesn’t fit in the previous categories.

`data_files` specifies a sequence of `(directory, files)` pairs in the following way:

```
setup(...,
  data_files=[
    ('bitmaps', ['bm/b1.gif', 'bm/b2.gif']),
    ('config', ['cfg/data.cfg']),
    ('/etc/init.d', ['init-script'])
  ]
)
```

Note that you can specify the directory names where the data files will be installed, but you cannot rename the data files themselves.

Each `(directory, files)` pair in the sequence specifies the installation directory and the files to install there. If `directory` is a relative path, it is interpreted relative to the installation prefix (Python’s `sys.prefix` for pure-Python packages, `sys.exec_prefix` for packages that contain extension modules). Each file name in `files` is interpreted relative to the `setup.py` script at the top of the package source distribution. No directory information from `files` is used to determine the final location of the installed file; only the name of the file is used.

You can specify the `data_files` options as a simple sequence of files without specifying a target directory, but this is not recommended, and the `install` command will print a warning in this case. To install data files directly in the target directory, an empty string should be given as the directory. Changed in version 3.1: All the files that match `data_files` will be added to the MANIFEST file if no template is provided. See `Specifying the files to distribute`.

### 2.8 Additional meta-data

The setup script may include additional meta-data beyond the name and version. This information includes:
### Meta-Data

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Value</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>name of the package</td>
<td>short string</td>
<td>(1)</td>
</tr>
<tr>
<td>version</td>
<td>version of this release</td>
<td>short string</td>
<td>(1)(2)</td>
</tr>
<tr>
<td>author</td>
<td>package author’s name</td>
<td>short string</td>
<td>(3)</td>
</tr>
<tr>
<td>author_email</td>
<td>email address of the package author</td>
<td>email address</td>
<td>(3)</td>
</tr>
<tr>
<td>maintainer</td>
<td>package maintainer’s name</td>
<td>short string</td>
<td>(3)</td>
</tr>
<tr>
<td>maintainer_email</td>
<td>email address of the package maintainer</td>
<td>email address</td>
<td>(3)</td>
</tr>
<tr>
<td>url</td>
<td>home page for the package</td>
<td>URL</td>
<td>(1)</td>
</tr>
<tr>
<td>description</td>
<td>short, summary description of the package</td>
<td>short string</td>
<td></td>
</tr>
<tr>
<td>long_description</td>
<td>longer description of the package</td>

</tr>
<tr>
<td>platforms</td>
<td>a list of platforms</td>
<td>list of strings</td>
<td></td>
</tr>
<tr>
<td>license</td>
<td>license for the package</td>
<td>short string</td>
<td>(6)</td>
</tr>
</tbody>
</table>

**Notes:**

1. These fields are required.
2. It is recommended that versions take the form `major.minor[.patch[.sub]]`.
3. Either the author or the maintainer must be identified. If maintainer is provided, distutils lists it as the author in `PKG-INFO`.
4. These fields should not be used if your package is to be compatible with Python versions prior to 2.2.3 or 2.3. The list is available from the PyPI website.
5. The `long_description` field is used by PyPI when you are registering a package, to build its home page.
6. The `license` field is a text indicating the license covering the package where the license is not a selection from the “License” Trove classifiers. See the `Classifier` field. Notice that there’s a licence distribution option which is deprecated but still acts as an alias for `license`.

*short string*  A single line of text, not more than 200 characters.

*long string*  Multiple lines of plain text in reStructuredText format (see http://docutils.sf.net/).

*list of strings*  See below.

Encoding the version information is an art in itself. Python packages generally adhere to the version format `major.minor[.patch[.sub]]`. The major number is 0 for initial, experimental releases of software. It is incremented for releases that represent major milestones in a package. The minor number is incremented when important new features are added to the package. The patch number increments when bug-fix releases are made. Additional trailing version information is sometimes used to indicate sub-releases. These are “a1,a2,...,aN” (for alpha releases, where functionality and API may change), “b1,b2,...,bN” (for beta releases, which only fix bugs) and “pr1,pr2,...,prN” (for final pre-release release testing). Some examples:

**0.1.0** the first, experimental release of a package

**1.0.1a2** the second alpha release of the first patch version of 1.0

`classifiers` are specified in a Python list:

```python
setup(...,
    classifiers=[
        'Development Status :: 4 - Beta',
        'Environment :: Console',
        'Environment :: Web Environment',
        'Intended Audience :: End Users/Desktop',
        'Intended Audience :: Developers',
        'Intended Audience :: System Administrators',
        'License :: OSI Approved :: Python Software Foundation License',
        'Operating System :: MacOS :: MacOS X',
        'Operating System :: Microsoft :: Windows',
        'Operating System :: POSIX',
    ]
)```

---

Chapter 2. Writing the Setup Script
If you wish to include classifiers in your setup.py file and also wish to remain backwards-compatible with Python releases prior to 2.2.3, then you can include the following code fragment in your setup.py before the setup() call.

```python
# patch distutils if it can't cope with the "classifiers" or
# "download_url" keywords
from sys import version
if version < '2.2.3':
    from distutils.dist import DistributionMetadata
    DistributionMetadata.classifiers = None
    DistributionMetadata.download_url = None
```

### 2.9 Debugging the setup script

Sometimes things go wrong, and the setup script doesn’t do what the developer wants.

Distutils catches any exceptions when running the setup script, and print a simple error message before the script is terminated. The motivation for this behaviour is to not confuse administrators who don’t know much about Python and are trying to install a package. If they get a big long traceback from deep inside the guts of Distutils, they may think the package or the Python installation is broken because they don’t read all the way down to the bottom and see that it’s a permission problem.

On the other hand, this doesn’t help the developer to find the cause of the failure. For this purpose, the DISTUTILS_DEBUG environment variable can be set to anything except an empty string, and distutils will now print detailed information what it is doing, and prints the full traceback in case an exception occurs.
Often, it’s not possible to write down everything needed to build a distribution \textit{a priori}: you may need to get some information from the user, or from the user’s system, in order to proceed. As long as that information is fairly simple—a list of directories to search for C header files or libraries, for example—then providing a configuration file, \texttt{setup.cfg}, for users to edit is a cheap and easy way to solicit it. Configuration files also let you provide default values for any command option, which the installer can then override either on the command-line or by editing the config file.

The setup configuration file is a useful middle-ground between the setup script—which, ideally, would be opaque to installers\footnote{This ideal probably won’t be achieved until auto-configuration is fully supported by the Distutils.}—and the command-line to the setup script, which is outside of your control and entirely up to the installer. In fact, \texttt{setup.cfg} (and any other Distutils configuration files present on the target system) are processed after the contents of the setup script, but before the command-line. This has several useful consequences:

- installers can override some of what you put in \texttt{setup.py} by editing \texttt{setup.cfg}
- you can provide non-standard defaults for options that are not easily set in \texttt{setup.py}
- installers can override anything in \texttt{setup.cfg} using the command-line options to \texttt{setup.py}

The basic syntax of the configuration file is simple:

```
[command]
option=value
...
```

where \texttt{command} is one of the Distutils commands (e.g. \texttt{build.py}, \texttt{install}), and \texttt{option} is one of the options that command supports. Any number of options can be supplied for each command, and any number of command sections can be included in the file. Blank lines are ignored, as are comments, which run from a ‘\#’ character until the end of the line. Long option values can be split across multiple lines simply by indenting the continuation lines.

You can find out the list of options supported by a particular command with the universal --\texttt{help} option, e.g.

```
> python setup.py --help build_ext
[...]
Options for ‘build_ext’ command:
--build-lib (-b) directory for compiled extension modules
--build-temp (-t) directory for temporary files (build by-products)
--inplace (-i) ignore build-lib and put compiled extensions into the
source directory alongside your pure Python modules
--include-dirs (-I) list of directories to search for header files
--define (-D) C preprocessor macros to define
--undef (-U) C preprocessor macros to undefine
--swig-opts list of SWIG command line options
[...]
```
Distributing Python Modules, Release 3.3.3

Note that an option spelled `--foo-bar` on the command-line is spelled `foo_bar` in configuration files.

For example, say you want your extensions to be built “in-place”—that is, you have an extension `pkg.ext`, and you want the compiled extension file (`.so` on Unix, say) to be put in the same source directory as your pure Python modules `pkg.mod1` and `pkg.mod2`. You can always use the `--inplace` option on the command-line to ensure this:

```
python setup.py build_ext --inplace
```

But this requires that you always specify the `build_ext` command explicitly, and remember to provide `--inplace`. An easier way is to “set and forget” this option, by encoding it in `setup.cfg`, the configuration file for this distribution:

```
[build_ext]
inplace=1
```

This will affect all builds of this module distribution, whether or not you explicitly specify `build_ext`. If you include `setup.cfg` in your source distribution, it will also affect end-user builds—which is probably a bad idea for this option, since always building extensions in-place would break installation of the module distribution. In certain peculiar cases, though, modules are built right in their installation directory, so this is conceivably a useful ability. (Distributing extensions that expect to be built in their installation directory is almost always a bad idea, though.)

Another example: certain commands take a lot of options that don’t change from run to run; for example, `bdist_rpm` needs to know everything required to generate a “spec” file for creating an RPM distribution. Some of this information comes from the setup script, and some is automatically generated by the Distutils (such as the list of files installed). But some of it has to be supplied as options to `bdist_rpm`, which would be very tedious to do on the command-line for every run. Hence, here is a snippet from the Distutils’ own `setup.cfg`:

```
[bdist_rpm]
release = 1
packager = Greg Ward <gward@python.net>
doc_files = CHANGES.txt
            README.txt
            USAGE.txt
            doc/
            examples/
```

Note that the `doc_files` option is simply a whitespace-separated string split across multiple lines for readability.

See Also:

`inst-config-syntax` in “Installing Python Modules” More information on the configuration files is available in the manual for system administrators.
CREATING A SOURCE DISTRIBUTION

As shown in section A Simple Example, you use the `sdist` command to create a source distribution. In the simplest case,

```python
python setup.py sdist
```

(assuming you haven’t specified any `sdist` options in the setup script or config file), `sdist` creates the archive of the default format for the current platform. The default format is a gzip’ed tar file (.tar.gz) on Unix, and ZIP file on Windows.

You can specify as many formats as you like using the `--formats` option, for example:

```python
python setup.py sdist --formats=gztar,zip
```

to create a gzipped tarball and a zip file. The available formats are:

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>zip</td>
<td>zip file (.zip)</td>
<td>(1),(3)</td>
</tr>
<tr>
<td>gztar</td>
<td>gzip’ed tar file (.tar.gz)</td>
<td>(2),(4)</td>
</tr>
<tr>
<td>bztar</td>
<td>bzip2’ed tar file (.tar.bz2)</td>
<td>(4)</td>
</tr>
<tr>
<td>ztar</td>
<td>compressed tar file (.tar.Z)</td>
<td>(4)</td>
</tr>
<tr>
<td>tar</td>
<td>tar file (.tar)</td>
<td>(4)</td>
</tr>
</tbody>
</table>

Notes:

1. default on Windows
2. default on Unix
3. requires either external `zip` utility or `zipfile` module (part of the standard Python library since Python 1.6)
4. requires external utilities: `tar` and possibly one of `gzip`, `bzip2`, or `compress`

### 4.1 Specifying the files to distribute

If you don’t supply an explicit list of files (or instructions on how to generate one), the `sdist` command puts a minimal default set into the source distribution:

- all Python source files implied by the `py_modules` and `packages` options
- all C source files mentioned in the `ext_modules` or `libraries` options (See Installing Scripts.)
- scripts identified by the `scripts` option
- anything that looks like a test script: `test/test*.py` (currently, the Distutils don’t do anything with test scripts except include them in source distributions, but in the future there will be a standard for testing Python module distributions)
- `README.txt` (or `README`), `setup.py` (or whatever you called your setup script), and `setup.cfg`
- all files that matches the `package_data` metadata. See Installing Package Data.
• all files that matches the data_files metadata. See Installing Additional Files.

Sometimes this is enough, but usually you will want to specify additional files to distribute. The typical way to do this is to write a manifest template, called MANIFEST.in by default. The manifest template is just a list of instructions for how to generate your manifest file, MANIFEST, which is the exact list of files to include in your source distribution. The sdist command processes this template and generates a manifest based on its instructions and what it finds in the filesystem.

If you prefer to roll your own manifest file, the format is simple: one filename per line, regular files (or symlinks to them) only. If you do supply your own MANIFEST, you must specify everything: the default set of files described above does not apply in this case. Changed in version 3.1: An existing generated MANIFEST will be regenerated without sdist comparing its modification time to the one of MANIFEST.in or setup.py. Changed in version 3.1.3: MANIFEST files start with a comment indicating they are generated. Files without this comment are not overwritten or removed. Changed in version 3.2.2: sdist will read a MANIFEST file if no MANIFEST.in exists, like it used to do. The manifest template has one command per line, where each command specifies a set of files to include or exclude from the source distribution. For an example, again we turn to the Distutils’ own manifest template:

```
include *.txt
recursive-include examples *.txt *.py
prune examples/sample?/build
```

The meanings should be fairly clear: include all files in the distribution root matching *.txt, all files anywhere under the examples directory matching *.txt or *.py, and exclude all directories matching examples/sample?/build. All of this is done after the standard include set, so you can exclude files from the standard set with explicit instructions in the manifest template. (Or, you can use the --no-defaults option to disable the standard set entirely.) There are several other commands available in the manifest template mini-language; see section Creating a source distribution: the sdist command.

The order of commands in the manifest template matters: initially, we have the list of default files as described above, and each command in the template adds to or removes from that list of files. Once we have fully processed the manifest template, we remove files that should not be included in the source distribution:

• all files in the Distutils “build” tree (default build/)
• all files in directories named RCS,CVS,.svn,.hg,.git,.bzr or _darcs

Now we have our complete list of files, which is written to the manifest for future reference, and then used to build the source distribution archive(s).

You can disable the default set of included files with the --no-defaults option, and you can disable the standard exclude set with --no-prune.

Following the Distutils’ own manifest template, let’s trace how the sdist command builds the list of files to include in the Distutils source distribution:

1. include all Python source files in the distutils and distutils/command subdirectories (because packages corresponding to those two directories were mentioned in the packages option in the setup script—see section Writing the Setup Script)
2. include README.txt, setup.py, and setup.cfg (standard files)
3. include test/test*.py (standard files)
4. include *.txt in the distribution root (this will find README.txt a second time, but such redundancies are weeded out later)
5. include anything matching *.txt or *.py in the sub-tree under examples,
6. exclude all files in the sub-trees starting at directories matching examples/sample?/build—this may exclude files included by the previous two steps, so it’s important that the prune command in the manifest template comes after the recursive-include command
7. exclude the entire build tree, and any RCS,CVS,.svn,.hg,.git,.bzr and _darcs directories
Just like in the setup script, file and directory names in the manifest template should always be slash-separated; the Distutils will take care of converting them to the standard representation on your platform. That way, the manifest template is portable across operating systems.

### 4.2 Manifest-related options

The normal course of operations for the `sdist` command is as follows:

- if the manifest file (`MANIFEST` by default) exists and the first line does not have a comment indicating it is generated from `MANIFEST.in`, then it is used as is, unaltered
- if the manifest file doesn’t exist or has been previously automatically generated, read `MANIFEST.in` and create the manifest
- if neither `MANIFEST` nor `MANIFEST.in` exist, create a manifest with just the default file set
- use the list of files now in `MANIFEST` (either just generated or read in) to create the source distribution archive(s)

There are a couple of options that modify this behaviour. First, use the `--no-defaults` and `--no-prune` to disable the standard “include” and “exclude” sets.

Second, you might just want to (re)generate the manifest, but not create a source distribution:

```bash
python setup.py dist --manifest-only
```

`-o` is a shortcut for `--manifest-only`. 
CREATING BUILT DISTRIBUTIONS

A “built distribution” is what you’re probably used to thinking of either as a “binary package” or an “installer” (depending on your background). It’s not necessarily binary, though, because it might contain only Python source code and/or byte-code; and we don’t call it a package, because that word is already spoken for in Python. (And “installer” is a term specific to the world of mainstream desktop systems.)

A built distribution is how you make life as easy as possible for installers of your module distribution: for users of RPM-based Linux systems, it’s a binary RPM; for Windows users, it’s an executable installer; for Debian-based Linux users, it’s a Debian package; and so forth. Obviously, no one person will be able to create built distributions for every platform under the sun, so the Distutils are designed to enable module developers to concentrate on their specialty—writing code and creating source distributions—while an intermediary species called packagers springs up to turn source distributions into built distributions for as many platforms as there are packagers.

Of course, the module developer could be his own packager; or the packager could be a volunteer “out there” somewhere who has access to a platform which the original developer does not; or it could be software periodically grabbing new source distributions and turning them into built distributions for as many platforms as the software has access to. Regardless of who they are, a packager uses the setup script and the bdist command family to generate built distributions.

As a simple example, if I run the following command in the Distutils source tree:

```
python setup.py bdist
```

then the Distutils builds my module distribution (the Distutils itself in this case), does a “fake” installation (also in the build directory), and creates the default type of built distribution for my platform. The default format for built distributions is a “dumb” tar file on Unix, and a simple executable installer on Windows. (That tar file is considered “dumb” because it has to be unpacked in a specific location to work.)

Thus, the above command on a Unix system creates Distutils-1.0.plat.tar.gz; unpacking this tarball from the right place installs the Distutils just as though you had downloaded the source distribution and run python setup.py install. (The “right place” is either the root of the filesystem or Python’s prefix directory, depending on the options given to the bdist_dumb command; the default is to make dumb distributions relative to prefix.)

Obviously, for pure Python distributions, this isn’t any simpler than just running python setup.py install—but for non-pure distributions, which include extensions that would need to be compiled, it can mean the difference between someone being able to use your extensions or not. And creating “smart” built distributions, such as an RPM package or an executable installer for Windows, is far more convenient for users even if your distribution doesn’t include any extensions.

The bdist command has a --formats option, similar to the sdist command, which you can use to select the types of built distribution to generate: for example,

```
python setup.py bdist --format=zip
```

would, when run on a Unix system, create Distutils-1.0.plat.zip—again, this archive would be unpacked from the root directory to install the Distutils.

The available formats for built distributions are:
Distributing Python Modules, Release 3.3.3

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>gztar</td>
<td>gzipped tar file (.tar.gz)</td>
<td>(1),(3)</td>
</tr>
<tr>
<td>ztar</td>
<td>compressed tar file (.tar.Z)</td>
<td>(3)</td>
</tr>
<tr>
<td>tar</td>
<td>tar file (.tar)</td>
<td>(3)</td>
</tr>
<tr>
<td>zip</td>
<td>zip file (.zip)</td>
<td>(2),(4)</td>
</tr>
<tr>
<td>rpm</td>
<td>RPM</td>
<td>(5)</td>
</tr>
<tr>

<td>HP-UX swinstall</td>
<td></td>
</tr>
<tr>
<td>wininst</td>
<td>self-extracting ZIP file for Windows</td>
<td>(4)</td>
</tr>
<tr>
<td>msi</td>
<td>Windows Installer</td>
<td></td>
</tr>
</tbody>
</table>

Notes:

1. default on Unix
2. default on Windows
3. requires external utilities: tar and possibly one of gzip, bzip2, or compress
4. requires either external zip utility or zipfile module (part of the standard Python library since Python 1.6)
5. requires external rpm utility, version 3.0.4 or better (use rpm --version to find out which version you have)

You don’t have to use the bdist command with the --formats option; you can also use the command that directly implements the format you’re interested in. Some of these bdist “sub-commands” actually generate several similar formats; for instance, the bdist_dumb command generates all the “dumb” archive formats (tar, ztar, gztar, and zip), and bdist_rpm generates both binary and source RPMs. The bdist sub-commands, and the formats generated by each, are:

<table>
<thead>
<tr>
<th>Command</th>
<th>Formats</th>
</tr>
</thead>
<tbody>
<tr>
<td>bdist_dumb</td>
<td>tar, ztar, gztar, zip</td>
</tr>
<tr>
<td>bdist_rpm</td>
<td>rpm, srpm</td>
</tr>
<tr>
<td>bdist_wininst</td>
<td>wininst</td>
</tr>
<tr>
<td>bdist_msi</td>
<td>msi</td>
</tr>
</tbody>
</table>

The following sections give details on the individual bdist_* commands.

5.1 Creating RPM packages

The RPM format is used by many popular Linux distributions, including Red Hat, SuSE, and Mandrake. If one of these (or any of the other RPM-based Linux distributions) is your usual environment, creating RPM packages for other users of that same distribution is trivial. Depending on the complexity of your module distribution and differences between Linux distributions, you may also be able to create RPMs that work on different RPM-based distributions.

The usual way to create an RPM of your module distribution is to run the bdist_rpm command:

```bash
python setup.py bdist_rpm
```

or the bdist command with the --format option:

```bash
python setup.py bdist --formats=rpm
```

The former allows you to specify RPM-specific options; the latter allows you to easily specify multiple formats in one run. If you need to do both, you can explicitly specify multiple bdist_* commands and their options:

```bash
python setup.py bdist_rpm --packager="John Doe <jdoe@example.org>" \ bdist_wininst --target-version="2.0"
```

Creating RPM packages is driven by a .spec file, much as using the Distutils is driven by the setup script. To make your life easier, the bdist_rpm command normally creates a .spec file based on the information you
supply in the setup script, on the command line, and in any Distutils configuration files. Various options and
sections in the .spec file are derived from options in the setup script as follows:

<table>
<thead>
<tr>
<th>RPM .spec file option or section</th>
<th>Distutils setup script option</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>name</td>
</tr>
<tr>
<td>Summary (in preamble)</td>
<td>description</td>
</tr>
<tr>
<td>Version</td>
<td>version</td>
</tr>
<tr>
<td>Vendor</td>
<td>author and author_email or — &amp; maintainer and maintainer_email</td>
</tr>
<tr>
<td>Copyright</td>
<td>license</td>
</tr>
<tr>
<td>Url</td>
<td>url</td>
</tr>
<tr>
<td>@description (section)</td>
<td>long_description</td>
</tr>
</tbody>
</table>

Additionally, there are many options in .spec files that don’t have corresponding options in the setup script.
Most of these are handled through options to the bdist_rpm command as follows:

<table>
<thead>
<tr>
<th>RPM .spec file option or section</th>
<th>bdist_rpm option</th>
<th>default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Release</td>
<td>release</td>
<td>“1”</td>
</tr>
<tr>
<td>Group</td>
<td>group</td>
<td>“Development/Libraries” (see above)</td>
</tr>
<tr>
<td>Vendor</td>
<td>vendor</td>
<td>(none)</td>
</tr>
<tr>
<td>Packager</td>
<td>package</td>
<td>(none)</td>

Obviously, supplying even a few of these options on the command-line would be tedious and error-prone, so it’s
usually best to put them in the setup configuration file, setup.cfg—see section Writing the Setup Configuration
File. If you distribute or package many Python module distributions, you might want to put options that apply to
all of them in your personal Distutils configuration file (~/.pydistutils.cfg).

There are three steps to building a binary RPM package, all of which are handled automatically by the Distutils:

1. create a .spec file, which describes the package (analogous to the Distutils setup script; in fact, much of
   the information in the setup script winds up in the .spec file)
2. create the source RPM
3. create the “binary” RPM (which may or may not contain binary code, depending on whether your module
distribution contains Python extensions)

Normally, RPM bundles the last two steps together; when you use the Distutils, all three steps are typically bundled
together.

If you wish, you can separate these three steps. You can use the --spec-only option to make bdist_rpm just create the .spec file and exit; in this case, the .spec file will be written to the “distribution directory”—
normally dist/, but customizable with the --dist-dir option. (Normally, the .spec file winds up deep in
the “build tree,” in a temporary directory created by bdist_rpm.)

5.2 Creating Windows Installers

Executable installers are the natural format for binary distributions on Windows. They display a nice graphical
user interface, display some information about the module distribution to be installed taken from the metadata in
the setup script, let the user select a few options, and start or cancel the installation.

Since the metadata is taken from the setup script, creating Windows installers is usually as easy as running:

python setup.py bdist_wininst

5.2. Creating Windows Installers
or the `bdist` command with the `--formats` option:

```
python setup.py bdist --formats=wininst
```

If you have a pure module distribution (only containing pure Python modules and packages), the resulting installer will be version independent and have a name like `foo-1.0.win32.exe`. These installers can even be created on Unix platforms or Mac OS X.

If you have a non-pure distribution, the extensions can only be created on a Windows platform, and will be Python version dependent. The installer filename will reflect this and now has the form `foo-1.0.win32-py2.0.exe`. You have to create a separate installer for every Python version you want to support.

The installer will try to compile pure modules into bytecode after installation on the target system in normal and optimizing mode. If you don’t want this to happen for some reason, you can run the `bdist_wininst` command with the `--no-target-compile` and/or the `--no-target-optimize` option.

By default the installer will display the cool “Python Powered” logo when it is run, but you can also supply your own 152x261 bitmap which must be a Windows .bmp file with the `--bitmap` option.

The installer will also display a large title on the desktop background window when it is run, which is constructed from the name of your distribution and the version number. This can be changed to another text by using the `--title` option.

The installer file will be written to the “distribution directory” — normally `dist/`, but customizable with the `--dist-dir` option.

### 5.3 Cross-compiling on Windows

Starting with Python 2.6, distutils is capable of cross-compiling between Windows platforms. In practice, this means that with the correct tools installed, you can use a 32bit version of Windows to create 64bit extensions and vice-versa.

To build for an alternate platform, specify the `--plat-name` option to the build command. Valid values are currently ‘win32’, ‘win-amd64’ and ‘win-ia64’. For example, on a 32bit version of Windows, you could execute:

```
python setup.py build --plat-name=win-amd64
```

to build a 64bit version of your extension. The Windows Installers also support this option, so the command:

```
python setup.py build --plat-name=win-amd64 bdist_wininst
```

would create a 64bit installation executable on your 32bit version of Windows.

To cross-compile, you must download the Python source code and cross-compile Python itself for the platform you are targeting - it is not possible from a binary installation of Python (as the .lib etc file for other platforms are not included.) In practice, this means the user of a 32 bit operating system will need to use Visual Studio 2008 to open the `PCBuild/PCbuild.sln` solution in the Python source tree and build the “x64” configuration of the ‘pythoncore’ project before cross-compiling extensions is possible.

Note that by default, Visual Studio 2008 does not install 64bit compilers or tools. You may need to reexecute the Visual Studio setup process and select these tools (using Control Panel->[Add/Remove] Programs is a convenient way to check or modify your existing install.)

#### 5.3.1 The Postinstallation script

Starting with Python 2.3, a postinstallation script can be specified with the `--install-script` option. The basename of the script must be specified, and the script filename must also be listed in the scripts argument to the setup function.

This script will be run at installation time on the target system after all the files have been copied, with `argv[1]` set to `-install`, and again at uninstallation time before the files are removed with `argv[1]` set to `-remove`.

The installation script runs embedded in the windows installer, every output (sys.stdout, sys.stderr) is redirected into a buffer and will be displayed in the GUI after the script has finished.
Some functions especially useful in this context are available as additional built-in functions in the installation script.

**directory_created** *(path)*

**file_created** *(path)*

These functions should be called when a directory or file is created by the postinstall script at installation time. It will register path with the uninstaller, so that it will be removed when the distribution is uninstalled.

To be safe, directories are only removed if they are empty.

**get_special_folder_path** *(csidl_string)*

This function can be used to retrieve special folder locations on Windows like the Start Menu or the Desktop. It returns the full path to the folder. csidl_string must be one of the following strings:

"CSIDL_APPDATA"

"CSIDL_COMMON_STARTMENU"
"CSIDL_STARTMENU"

"CSIDL_COMMON_DESKTOPDIRECTORY"
"CSIDL_DESKTOPDIRECTORY"

"CSIDL_COMMON_STARTUP"
"CSIDL_STARTUP"

"CSIDL_COMMON_PROGRAMS"
"CSIDL_PROGRAMS"

"CSIDL_FONTS"

If the folder cannot be retrieved, OSError is raised.

Which folders are available depends on the exact Windows version, and probably also the configuration. For details refer to Microsoft’s documentation of the SHGetSpecialFolderPath() function.

**create_shortcut** *(target, description, filename[, arguments[, workdir[, iconpath[, iconindex]]]])*

This function creates a shortcut. target is the path to the program to be started by the shortcut. description is the description of the shortcut. filename is the title of the shortcut that the user will see. arguments specifies the command line arguments, if any. workdir is the working directory for the program. iconpath is the file containing the icon for the shortcut, and iconindex is the index of the icon in the file iconpath. Again, for details consult the Microsoft documentation for the IShellLink interface.

### 5.4 Vista User Access Control (UAC)

Starting with Python 2.6, bdist_wininst supports a `--user-access-control` option. The default is ‘none’ (meaning no UAC handling is done), and other valid values are ‘auto’ (meaning prompt for UAC elevation if Python was installed for all users) and ‘force’ (meaning always prompt for elevation).
The Python Package Index (PyPI) holds meta-data describing distributions packaged with distutils, as well as package data like distribution files if the package author wishes.

Distutils exposes two commands for submitting package data to PyPI: the register command for submitting meta-data to PyPI and the upload command for submitting distribution files. Both commands read configuration data from a special file called the .pypirc file. PyPI displays a home page for each package created from the long_description submitted by the register command.

6.1 Registering Packages

The distutils command register is used to submit your distribution’s meta-data to the index. It is invoked as follows:

```
python setup.py register
```

Distutils will respond with the following prompt:

```
running register
We need to know who you are, so please choose either:
1. use your existing login,
2. register as a new user,
3. have the server generate a new password for you (and email it to you), or
4. quit
Your selection [default 1]:
```

Note: if your username and password are saved locally, you will not see this menu.

If you have not registered with PyPI, then you will need to do so now. You should choose option 2, and enter your details as required. Soon after submitting your details, you will receive an email which will be used to confirm your registration.

Once you are registered, you may choose option 1 from the menu. You will be prompted for your PyPI username and password, and register will then submit your meta-data to the index.

You may submit any number of versions of your distribution to the index. If you alter the meta-data for a particular version, you may submit it again and the index will be updated.

PyPI holds a record for each (name, version) combination submitted. The first user to submit information for a given name is designated the Owner of that name. They may submit changes through the register command or through the web interface. They may also designate other users as Owners or Maintainers. Maintainers may edit the package information, but not designate other Owners or Maintainers.

By default PyPI displays only the newest version of a given package. The web interface lets one change this default behavior and manually select which versions to display and hide.
6.2 Uploading Packages

The distutils command `upload` pushes the distribution files to PyPI. The command is invoked immediately after building one or more distribution files. For example, the command

```bash
python setup.py sdist bdist_wininst upload
```

will cause the source distribution and the Windows installer to be uploaded to PyPI. Note that these will be uploaded even if they are built using an earlier invocation of `setup.py`, but that only distributions named on the command line for the invocation including the `upload` command are uploaded.

The `upload` command uses the username, password, and repository URL from the `$HOME/.pypirc` file (see section The `.pypirc` file for more on this file). If a `register` command was previously called in the same command, and if the password was entered in the prompt, `upload` will reuse the entered password. This is useful if you do not want to store a clear text password in the `$HOME/.pypirc` file.

You can specify another PyPI server with the `--repository=url` option:

```bash
python setup.py sdist bdist_wininst upload -r http://example.com/pypi
```

See section The `.pypirc` file for more on defining several servers.

You can use the `--sign` option to tell `upload` to sign each uploaded file using GPG (GNU Privacy Guard). The `gpg` program must be available for execution on the system `PATH`. You can also specify which key to use for signing using the `--identity=name` option.

Other `upload` options include `--repository=url` or `--repository=section` where `url` is the url of the server and `section` the name of the section in `$HOME/.pypirc`, and `--show-response` (which displays the full response text from the PyPI server for help in debugging upload problems).

6.3 The `.pypirc` file

The format of the `.pypirc` file is as follows:

```ini
[distutils]
index-servers = pypi

[pypi]
repository: <repository-url>
username: <username>
password: <password>
```

The `distutils` section defines a `index-servers` variable that lists the name of all sections describing a repository.

Each section describing a repository defines three variables:

- `username`, which is the registered username on the PyPI server.
- `password`, that will be used to authenticate. If omitted the user will be prompt to type it when needed.

If you want to define another server a new section can be created and listed in the `index-servers` variable:

```ini
[distutils]
index-servers = pypi
other

[other]
repository: <repository-url>
username: <username>
```
password: <password>

[other]
repository: http://example.com/pypi
username: <username>
password: <password>

register can then be called with the -r option to point the repository to work with:

python setup.py register -r http://example.com/pypi

For convenience, the name of the section that describes the repository may also be used:

python setup.py register -r other

6.4 PyPI package display

The long_description field plays a special role at PyPI. It is used by the server to display a home page for the registered package.

If you use the reStructuredText syntax for this field, PyPI will parse it and display an HTML output for the package home page.

The long_description field can be attached to a text file located in the package:

from distutils.core import setup

with open('README.txt') as file:
    long_description = file.read()

setup(name='Distutils',
      long_description=long_description)

In that case, README.txt is a regular reStructuredText text file located in the root of the package besides setup.py.

To prevent registering broken reStructuredText content, you can use the rst2html program that is provided by the docutils package and check the long_description from the command line:

$ python setup.py --long-description | rst2html.py > output.html

docutils will display a warning if there’s something wrong with your syntax. Because PyPI applies additional checks (e.g. by passing --no-raw to rst2html.py in the command above), being able to run the command above without warnings does not guarantee that PyPI will convert the content successfully.
This chapter provides a number of basic examples to help get started with distutils. Additional information about using distutils can be found in the Distutils Cookbook.

See Also:

Distutils Cookbook Collection of recipes showing how to achieve more control over distutils.

7.1 Pure Python distribution (by module)

If you’re just distributing a couple of modules, especially if they don’t live in a particular package, you can specify them individually using the `py_modules` option in the setup script.

In the simplest case, you’ll have two files to worry about: a setup script and the single module you’re distributing, `foo.py` in this example:

```python
<root>/
    setup.py
    foo.py
```

(In all diagrams in this section, `<root>` will refer to the distribution root directory.) A minimal setup script to describe this situation would be:

```python
from distutils.core import setup
setup(name='foo',
    version='1.0',
    py_modules=['foo'],
)
```

Note that the name of the distribution is specified independently with the `name` option, and there’s no rule that says it has to be the same as the name of the sole module in the distribution (although that’s probably a good convention to follow). However, the distribution name is used to generate filenames, so you should stick to letters, digits, underscores, and hyphens.

Since `py_modules` is a list, you can of course specify multiple modules, eg. if you’re distributing modules `foo` and `bar`, your setup might look like this:

```python
<root>/
    setup.py
    foo.py
    bar.py
```

and the setup script might be

```python
from distutils.core import setup
setup(name='foobar',
    version='1.0',
    py_modules=['foo', 'bar'],
)
```
You can put module source files into another directory, but if you have enough modules to do that, it’s probably easier to specify modules by package rather than listing them individually.

### 7.2 Pure Python distribution (by package)

If you have more than a couple of modules to distribute, especially if they are in multiple packages, it’s probably easier to specify whole packages rather than individual modules. This works even if your modules are not in a package; you can just tell the Distutils to process modules from the root package, and that works the same as any other package (except that you don’t have to have an `__init__.py` file).

The setup script from the last example could also be written as

```python
from distutils.core import setup
setup(name='foobar',
      version='1.0',
      packages=[''],
)
```

(The empty string stands for the root package.)

If those two files are moved into a subdirectory, but remain in the root package, e.g.:

```
<root>/
  setup.py
  src/
      foo.py
      bar.py
```

then you would still specify the root package, but you have to tell the Distutils where source files in the root package live:

```python
from distutils.core import setup
setup(name='foobar',
      version='1.0',
      package_dir={'': 'src'},
      packages=[''],
)
```

More typically, though, you will want to distribute multiple modules in the same package (or in sub-packages). For example, if the `foo` and `bar` modules belong in package `foobar`, one way to layout your source tree is

```
<root>/
  setup.py
  foobar/
      __init__.py
      foo.py
      bar.py
```

This is in fact the default layout expected by the Distutils, and the one that requires the least work to describe in your setup script:

```python
from distutils.core import setup
setup(name='foobar',
      version='1.0',
      packages=['foobar'],
)
```

If you want to put modules in directories not named for their package, then you need to use the `package_dir` option again. For example, if the `src` directory holds modules in the `foobar` package:

```
<root>/
  setup.py
  src/
      __init__.py
```
an appropriate setup script would be

```python
from distutils.core import setup
setup(name='foobar',
      version='1.0',
      package_dir={'foobar': 'src'},
      packages=['foobar'],
)
```

Or, you might put modules from your main package right in the distribution root:

```python
<root>/
   setup.py
   __init__.py
   foo.py
   bar.py
```

in which case your setup script would be

```python
from distutils.core import setup
setup(name='foobar',
      version='1.0',
      package_dir={'foobar': ''},
      packages=['foobar'],
)
```

(The empty string also stands for the current directory.)

If you have sub-packages, they must be explicitly listed in `packages`, but any entries in `package_dir` automatically extend to sub-packages. (In other words, the Distutils does not scan your source tree, trying to figure out which directories correspond to Python packages by looking for `__init__.py` files.) Thus, if the default layout grows a sub-package:

```python
<root>/
   setup.py
   foobar/
      __init__.py
      foo.py
      bar.py
   subfoo/
      __init__.py
      blah.py
```

then the corresponding setup script would be

```python
from distutils.core import setup
setup(name='foobar',
      version='1.0',
      packages=['foobar', 'foobar.subfoo'],
)
```

(Again, the empty string in `package_dir` stands for the current directory.)

### 7.3 Single extension module

Extension modules are specified using the `ext_modules` option. `package_dir` has no effect on where extension source files are found; it only affects the source for pure Python modules. The simplest case, a single extension module in a single C source file, is:
If the `foo` extension belongs in the root package, the setup script for this could be

```python
from distutils.core import setup
from distutils.extension import Extension
setup(name='foobar',
      version='1.0',
      ext_modules=[Extension('foo', ['foo.c'])],
)
```

If the extension actually belongs in a package, say `foopkg`, then

With exactly the same source tree layout, this extension can be put in the `foopkg` package simply by changing the name of the extension:

```python
from distutils.core import setup
from distutils.extension import Extension
setup(name='foobar',
      version='1.0',
      ext_modules=[Extension('foopkg.foo', ['foo.c'])],
)
```

### 7.4 Checking a package

The `check` command allows you to verify if your package meta-data meet the minimum requirements to build a distribution.

To run it, just call it using your `setup.py` script. If something is missing, `check` will display a warning.

Let’s take an example with a simple script:

```python
from distutils.core import setup
setup(name='foobar')
```

Running the `check` command will display some warnings:

```bash
$ python setup.py check
running check
warning: check: missing required meta-data: version, url
warning: check: missing meta-data: either (author and author_email) or (maintainer and maintainer_email) must be supplied
```

If you use the reStructuredText syntax in the `long_description` field and docutils is installed you can check if the syntax is fine with the `check` command, using the `restructuredtext` option.

For example, if the `setup.py` script is changed like this:

```python
from distutils.core import setup
desc = """\nMy description
"""
setup(name='foobar', version='1', author='tarek',
       author_email='tarek@ziade.org',
       url='http://example.com', long_description=desc)
```
Where the long description is broken, `check` will be able to detect it by using the `docutils` parser:

```bash
$ python setup.py check --restructuredtext
running check
warning: check: Title underline too short. (line 2)
warning: check: Could not finish the parsing.
```
EXTENDING DISTUTILS

Distutils can be extended in various ways. Most extensions take the form of new commands or replacements for existing commands. New commands may be written to support new types of platform-specific packaging, for example, while replacements for existing commands may be made to modify details of how the command operates on a package.

Most extensions of the distutils are made within setup.py scripts that want to modify existing commands; many simply add a few file extensions that should be copied into packages in addition to .py files as a convenience.

Most distutils command implementations are subclasses of the distutils.cmd.Command class. New commands may directly inherit from Command, while replacements often derive from Command indirectly, directly subclassing the command they are replacing. Commands are required to derive from Command.

8.1 Integrating new commands

There are different ways to integrate new command implementations into distutils. The most difficult is to lobby for the inclusion of the new features in distutils itself, and wait for (and require) a version of Python that provides that support. This is really hard for many reasons.

The most common, and possibly the most reasonable for most needs, is to include the new implementations with your setup.py script, and cause the distutils.core.setup() function use them:

```python
from distutils.command.build_py import build_py as _build_py
from distutils.core import setup

class build_py(_build_py):
    """Specialized Python source builder.""
    # implement whatever needs to be different...

setup(cmdclass={'build_py': build_py},
      ...
)
```

This approach is most valuable if the new implementations must be used to use a particular package, as everyone interested in the package will need to have the new command implementation.

Beginning with Python 2.4, a third option is available, intended to allow new commands to be added which can support existing setup.py scripts without requiring modifications to the Python installation. This is expected to allow third-party extensions to provide support for additional packaging systems, but the commands can be used for anything distutils commands can be used for. A new configuration option, command_packages (command-line option --command-packages), can be used to specify additional packages to be searched for modules implementing commands. Like all distutils options, this can be specified on the command line or in a configuration file. This option can only be set in the [global] section of a configuration file, or before any commands on the command line. If set in a configuration file, it can be overridden from the command line; setting it to an empty string on the command line causes the default to be used. This should never be set in a configuration file provided with a package.
This new option can be used to add any number of packages to the list of packages searched for command implementations; multiple package names should be separated by commas. When not specified, the search is only performed in the `distutils.command` package. When `setup.py` is run with the option `--command-packages distcmds,buildcmds`, however, the packages `distutils.command`, `distcmds`, and `buildcmds` will be searched in that order. New commands are expected to be implemented in modules of the same name as the command by classes sharing the same name. Given the example command line option above, the command `bdist_openpkg` could be implemented by the class `distcmds.bdist_openpkg.bdist_openpkg` or `buildcmds.bdist_openpkg.bdist_openpkg`.

### 8.2 Adding new distribution types

Commands that create distributions (files in the `dist/` directory) need to add `(command, filename)` pairs to `self.distribution.dist_files` so that `upload` can upload it to PyPI. The `filename` in the pair contains no path information, only the name of the file itself. In dry-run mode, pairs should still be added to represent what would have been created.
9.1 Installing modules: the install command family

The install command ensures that the build commands have been run and then runs the subcommands install_lib, install_data and install_scripts.

9.1.1 install_data

This command installs all data files provided with the distribution.

9.1.2 install_scripts

This command installs all (Python) scripts in the distribution.

9.2 Creating a source distribution: the sdist command

The manifest template commands are:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>include pat1 pat2 ...</td>
<td>include all files matching any of the listed patterns</td>
</tr>
<tr>
<td>exclude pat1 pat2 ...</td>
<td>exclude all files matching any of the listed patterns</td>
</tr>
<tr>
<td>recursive-include dir pat1</td>
<td>include all files under dir matching any of the listed patterns</td>
</tr>
<tr>
<td>pat2 ...</td>
<td></td>
</tr>
<tr>
<td>recursive-exclude dir pat1</td>
<td>exclude all files under dir matching any of the listed patterns</td>
</tr>
<tr>
<td>pat2 ...</td>
<td></td>
</tr>
<tr>
<td>global-include pat1 pat2 ...</td>
<td>include all files anywhere in the source tree matching — &amp; any of the listed patterns</td>
</tr>
<tr>
<td>global-exclude pat1 pat2 ...</td>
<td>exclude all files anywhere in the source tree matching — &amp; any of the listed patterns</td>
</tr>
<tr>
<td>prune dir</td>
<td>exclude all files under dir</td>
</tr>
<tr>
<td>graft dir</td>
<td>include all files under dir</td>
</tr>
</tbody>
</table>

The patterns here are Unix-style “glob” patterns: * matches any sequence of regular filename characters, ? matches any single regular filename character, and [range] matches any of the characters in range (e.g., a-z, a-zA-Z, a-f0-9_). The definition of “regular filename character” is platform-specific: on Unix it is anything except slash; on Windows anything except backslash or colon.
10.1 distutils.core — Core Distutils functionality

The distutils.core module is the only module that needs to be installed to use the Distutils. It provides the setup() function (which is called from the setup script). Indirectly provides the distutils.dist.Distribution and distutils.cmd.Command class.

distutils.core.setup(arguments)

The basic do-everything function that does most everything you could ever ask for from a Distutils method.

The setup function takes a large number of arguments. These are laid out in the following table.
<table>
<thead>
<tr>
<th>argument name</th>
<th>value</th>
<th>type</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the package</td>
<td>a string</td>
</tr>
<tr>
<td>version</td>
<td>The version number of the package; see <code>distutils.version</code></td>
<td>a string</td>
</tr>
<tr>
<td>description</td>
<td>A single line describing the package</td>
<td>a string</td>
</tr>
<tr>
<td>long_description</td>
<td>Longer description of the package</td>
<td>a string</td>
</tr>
<tr>
<td>author</td>
<td>The name of the package author</td>
<td>a string</td>
</tr>
<tr>
<td>author_email</td>
<td>The email address of the package author</td>
<td>a string</td>
</tr>
<tr>
<td>maintainer</td>
<td>The name of the current maintainer, if different from the author</td>
<td>a string</td>
</tr>
<tr>
<td>maintainer_email</td>
<td>The email address of the current maintainer, if different from the author</td>
<td>a string</td>
</tr>
<tr>
<td>url</td>
<td>A URL for the package (homepage)</td>
<td>a string</td>
</tr>
<tr>
<td>download_url</td>
<td>A URL to download the package</td>
<td>a string</td>
</tr>
<tr>
<td>packages</td>
<td>A list of Python packages that distutils will manipulate</td>
<td>a list of strings</td>
</tr>
<tr>
<td>py_modules</td>
<td>A list of Python modules that distutils will manipulate</td>
<td>a list of strings</td>
</tr>
<tr>
<td>scripts</td>
<td>A list of standalone script files to be built and installed</td>
<td>a list of strings</td>
</tr>
<tr>
<td>ext_modules</td>
<td>A list of Python extensions to be built</td>
<td>a list of instances of <code>distutils.core.Extension</code></td>
</tr>
<tr>
<td>classifiers</td>
<td>A list of categories for the package</td>
<td>a list of strings; valid classifiers are listed on PyPI.</td>
</tr>
<tr>
<td>distclass</td>
<td>the <code>Distribution</code> class to use</td>
<td>a subclass of <code>distutils.core.Distribution</code></td>
</tr>
<tr>
<td>script_name</td>
<td>The name of the setup.py script - defaults to <code>sys.argv[0]</code></td>

`distutils.core.run_setup(script_name[, script_args=None, stop_after='run'])`

Run a setup script in a somewhat controlled environment, and return the `distutils.dist.Distribution` instance that drives things. This is useful if you need to find out the distribution meta-data (passed as keyword args from `script` to `setup()`), or the contents of the config files or command-line.

`script_name` is a file that will be read and run with `exec()`. `sys.argv[0]` will be replaced with `script` for the duration of the call. `script_args` is a list of strings; if supplied, `sys.argv[1:]` will be replaced by `script_args` for the duration of the call.

`stop_after` tells `setup()` when to stop processing; possible values:
### 10.1. distutils.core — Core Distutils functionality

In addition, the `distutils.core` module exposed a number of classes that live elsewhere.

- **Extension** from `distutils.extension`
- **Command** from `distutils.cmd`
- **Distribution** from `distutils.dist`

A short description of each of these follows, but see the relevant module for the full reference.

#### class `distutils.core.Extension`

The `Extension` class describes a single C or C++ extension module in a setup script. It accepts the following keyword arguments in its constructor:

<table>
<thead>
<tr>
<th>value</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>init</code></td>
<td>Stop after the <code>Distribution</code> instance has been created and populated with the keyword arguments to <code>setup()</code></td>
</tr>
<tr>
<td><code>config</code></td>
<td>Stop after config files have been parsed (and their data stored in the <code>Distribution</code> instance)</td>
</tr>
<tr>
<td><code>commandline</code></td>
<td>Stop after the command-line (sys.argv[1:] or script_args) have been parsed (and the data stored in the <code>Distribution</code> instance.)</td>
</tr>
<tr>
<td><code>run</code></td>
<td>Stop after all commands have been run (the same as if <code>setup()</code> had been called in the usual way). This is the default value.</td>
</tr>
<tr>
<td>argument name</td>
<td>value</td>
</tr>
<tr>
<td>-----------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>name</td>
<td>the full name of the extension, including any packages — ie. not a filename or pathname, but Python dotted name</td>
</tr>
<tr>
<td>sources</td>
<td>list of source filenames, relative to the distribution root (where the setup script lives), in Unix form (slash-separated) for portability. Source files may be C, C++, SWIG (.i), platform-specific resource files, or whatever else is recognized by the build_ext command as source for a Python extension.</td>
</tr>
<tr>
<td>include_dirs</td>
<td>list of directories to search for C/C++ header files (in Unix form for portability)</td>
</tr>
<tr>
<td>define_macros</td>
<td>list of macros to define; each macro is defined using a 2-tuple (name, value), where value is either the string to define it to or None to define it without a particular value (equivalent of #define FOO in source or -DFOO on Unix C compiler command line)</td>
</tr>
<tr>
<td>undef_macros</td>
<td>list of macros to undefine explicitly</td>
</tr>
<tr>
<td>library_dirs</td>
<td>list of directories to search for C/C++ libraries at link time</td>
</tr>
<tr>
<td>libraries</td>
<td>list of library names (not filenames or paths) to link against</td>
</tr>
<tr>
<td>runtime_library_dirs</td>
<td>list of directories to search for C/C++ libraries at run time (for shared extensions, this is when the extension is loaded)</td>
</tr>
<tr>
<td>extra_objects</td>
<td>list of extra files to link with (eg. object files not implied by ‘sources’, static library that must be explicitly specified, binary resource files, etc.)</td>
</tr>
<tr>
<td>extra_compile_args</td>
<td>any extra platform- and compiler-specific information to use when compiling the source files in ‘sources’. For platforms and compilers where a command line makes sense, this is typically a list of command-line arguments, but for other platforms it could be anything.</td>
</tr>
<tr>
<td>extra_link_args</td>
<td>any extra platform- and compiler-specific information to use when linking object files together to create the extension (or to create a new static Python interpreter). Similar interpretation as for ‘extra_compile_args’.</td>
</tr>
<tr>
<td>export_symbols</td>
<td>list of symbols to be exported from a shared extension. Not used on all platforms, and not generally necessary for Python extensions, which typically export exactly one symbol: init + extension_name.</td>
</tr>
<tr>
<td>depends</td>
<td>list of files that the extension depends on extension language (i.e. ‘c’, ‘c++’, ‘objc’). Will be detected from the source extensions if not provided.</td>
</tr>
<tr>
<td>language</td>
<td>a string</td>
</tr>
<tr>
<td>optional</td>
<td>specifies that a build failure in the extension should not abort the build process, but simply skip the extension.</td>
</tr>
</tbody>
</table>

**class distutils.core.Distribution**

A **Distribution** describes how to build, install and package up a Python software package.

See the **setup()** function for a list of keyword arguments accepted by the Distribution constructor. **setuptools()** creates a Distribution instance.

**class distutils.core.Command**

A **Command** class (or rather, an instance of one of its subclasses) implement a single distutils command.

### 10.2 distutils.ccompiler — CCompiler base class

This module provides the abstract base class for the **CCompiler** classes. A **CCompiler** instance can be used for all the compile and link steps needed to build a single project. Methods are provided to set options for the compiler — macro definitions, include directories, link path, libraries and the like.

This module provides the following functions.
distutils.ccompiler.gen_lib_options(compiler, library_dirs, runtime_library_dirs, libraries)

Generate linker options for searching library directories and linking with specific libraries. libraries and library_dirs are, respectively, lists of library names (not filenames!) and search directories. Returns a list of command-line options suitable for use with some compiler (depending on the two format strings passed in).

distutils.ccompiler.gen_preprocess_options(macro, include_dirs)

Generate C pre-processor options (—D, —U, —I) as used by at least two types of compilers: the typical Unix compiler and Visual C++. macros is the usual thing, a list of 1- or 2-tuples, where (name,) means undefine (—U) macro name, and (name, value) means define (—D) macro name to value. include_dirs is just a list of directory names to be added to the header file search path (—I). Returns a list of command-line options suitable for either Unix compilers or Visual C++.

distutils.ccompiler.get_default_compiler(osname, platform)

Determine the default compiler to use for the given platform.

osname should be one of the standard Python OS names (i.e. the ones returned by os.name) and platform the common value returned by sys.platform for the platform in question.

The default values are os.name and sys.platform in case the parameters are not given.

distutils.ccompiler.new_compiler(plat=None, compiler=None, verbose=0, dry_run=0, force=0)

Factory function to generate an instance of some CCompiler subclass for the supplied platform/compiler combination. plat defaults to os.name (eg. ‘posix’, ‘nt’), and compiler defaults to the default compiler for that platform. Currently only ‘posix’ and ‘nt’ are supported, and the default compilers are “traditional Unix interface” (UnixCCompiler class) and Visual C++ (MSVCCompiler class). Note that it’s perfectly possible to ask for a Unix compiler object under Windows, and a Microsoft compiler object under Unix—if you supply a value for compiler, plat is ignored.

distutils.ccompiler.show_compilers()

Print list of available compilers (used by the --help-compiler options to build, build_ext, build_clib).

class distutils.ccompiler.CCompiler([verbose=0, dry_run=0, force=0])

The abstract base class CCompiler defines the interface that must be implemented by real compiler classes. The class also has some utility methods used by several compiler classes.

The basic idea behind a compiler abstraction class is that each instance can be used for all the compile/link steps in building a single project. Thus, attributes common to all of those compile and link steps — include directories, macros to define, libraries to link against, etc. — are attributes of the compiler instance. To allow for variability in how individual files are treated, most of those attributes may be varied on a per-compilation or per-link basis.

The constructor for each subclass creates an instance of the Compiler object. Flags are verbose (show verbose output), dry_run (don’t actually execute the steps) and force (rebuild everything, regardless of dependencies). All of these flags default to 0 (off). Note that you probably don’t want to instantiate CCompiler or one of its subclasses directly - use the distutils.CCompiler.new_compiler() factory function instead.

The following methods allow you to manually alter compiler options for the instance of the Compiler class.

add_include_dir(dir)

Add dir to the list of directories that will be searched for header files. The compiler is instructed to search directories in the order in which they are supplied by successive calls to add_include_dir().

set_include_dirs(dirs)

Set the list of directories that will be searched to dirs (a list of strings). Overrides any preceding calls to add_include_dir(); subsequent calls to add_include_dir() add to the list passed to set_include_dirs(). This does not affect any list of standard include directories that the compiler may search by default.

add_library(libname)

Add libname to the list of libraries that will be included in all links driven by this compiler object. Note that libname should *not* be the name of a file containing a library, but the name of the library

10.2. distutils.ccompiler — CCompiler base class 47
itself: the actual filename will be inferred by the linker, the compiler, or the compiler class (depending on the platform).

The linker will be instructed to link against libraries in the order they were supplied to \texttt{add_library()} and/or \texttt{set_libraries()}. It is perfectly valid to duplicate library names; the linker will be instructed to link against libraries as many times as they are mentioned.

\texttt{set_libraries (libnames)}

Set the list of libraries to be included in all links driven by this compiler object to \texttt{libnames} (a list of strings). This does not affect any standard system libraries that the linker may include by default.

\texttt{add_library_dir (dir)}

Add \texttt{dir} to the list of directories that will be searched for libraries specified to \texttt{add_library()} and \texttt{set_libraries()}. The linker will be instructed to search for libraries in the order they are supplied to \texttt{add_library_dir()} and/or \texttt{set_library_dirs()}.

\texttt{set_library_dirs (dirs)}

Set the list of library search directories to \texttt{dirs} (a list of strings). This does not affect any standard library search path that the linker may search by default.

\texttt{add_runtime_library_dir (dir)}

Add \texttt{dir} to the list of directories that will be searched for shared libraries at runtime.

\texttt{set_runtime_library_dirs (dirs)}

Set the list of directories to search for shared libraries at runtime to \texttt{dirs} (a list of strings). This does not affect any standard search path that the runtime linker may search by default.

\texttt{define_macro (name[, value=None])}

Define a preprocessor macro for all compilations driven by this compiler object. The optional parameter \texttt{value} should be a string; if it is not supplied, then the macro will be defined without an explicit value and the exact outcome depends on the compiler used.

\texttt{undefine_macro (name)}

Undefine a preprocessor macro for all compilations driven by this compiler object. If the same macro is defined by \texttt{define_macro()} and undefined by \texttt{undefine_macro()} the last call takes precedence (including multiple redefinitions or undefinitions). If the macro is redefined/undefined on a per-compilation basis (i.e. in the call to \texttt{compile()}), then that takes precedence.

\texttt{add_link_object (object)}

Add \texttt{object} to the list of object files (or analogues, such as explicitly named library files or the output of “resource compilers”) to be included in every link driven by this compiler object.

\texttt{set_link_objects (objects)}

Set the list of object files (or analogues) to be included in every link to \texttt{objects}. This does not affect any standard object files that the linker may include by default (such as system libraries).

The following methods implement methods for autodetection of compiler options, providing some functionality similar to GNU \texttt{autoconf}.

\texttt{detect_language (sources)}

Detect the language of a given file, or list of files. Uses the instance attributes \texttt{language_map} (a dictionary), and \texttt{language_order} (a list) to do the job.

\texttt{find_library_file (dirs, lib[, debug=0])}

Search the specified list of directories for a static or shared library file \texttt{lib} and return the full path to that file. If \texttt{debug} is true, look for a debugging version (if that makes sense on the current platform). Return \texttt{None} if \texttt{lib} wasn’t found in any of the specified directories.

\texttt{has_function (funcname[, includes=None, include_dirs=None, libraries=None, library_dirs=None])}

Return a boolean indicating whether \texttt{funcname} is supported on the current platform. The optional arguments can be used to augment the compilation environment by providing additional include files and paths and libraries and paths.

\texttt{library_dir_option (dir)}

Return the compiler option to add \texttt{dir} to the list of directories searched for libraries.
library_option(lib)
Return the compiler option to add dir to the list of libraries linked into the shared library or executable.

runtime_library_dir_option(dir)
Return the compiler option to add dir to the list of directories searched for runtime libraries.

set_executables(**args)
Define the executables (and options for them) that will be run to perform the various stages of compilation. The exact set of executables that may be specified here depends on the compiler class (via the 'executables' class attribute), but most will have:

<table>
<thead>
<tr>
<th>attribute</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>compiler</td>
<td>the C/C++ compiler</td>
</tr>
<tr>
<td>linker_so</td>
<td>linker used to create shared objects and libraries</td>
</tr>
<tr>
<td>linker_exe</td>
<td>linker used to create binary executables</td>
</tr>
<tr>
<td>archiver</td>
<td>static library creator</td>
</tr>
</tbody>
</table>

On platforms with a command-line (Unix, DOS/Windows), each of these is a string that will be split into executable name and (optional) list of arguments. (Splitting the string is done similarly to how Unix shells operate: words are delimited by spaces, but quotes and backslashes can override this. See distutils.util.split_quoted().)

The following methods invoke stages in the build process.

compile(sources[, output_dir=None, macros=None, include_dirs=None, debug=0, extra_preargs=None, extra_postargs=None, depends=None])
Compile one or more source files. Generates object files (e.g. transforms a .c file to a .o file.)

sources must be a list of filenames, most likely C/C++ files, but in reality anything that can be handled by a particular compiler and compiler class (eg. MSVCCompiler can handle resource files in sources). Return a list of object filenames, one per source filename in sources. Depending on the implementation, not all source files will necessarily be compiled, but all corresponding object filenames will be returned.

If output_dir is given, object files will be put under it, while retaining their original path component. That is, foo/bar.c normally compiles to foo/bar.o (for a Unix implementation); if output_dir is build, then it would compile to build/foo/bar.o.

macros, if given, must be a list of macro definitions. A macro definition is either a (name, value) 2-tuple or a (name,) 1-tuple. The former defines a macro; if the value is None, the macro is defined without an explicit value. The 1-tuple case undefines a macro. Later definitions/redefinitions/undefinitions take precedence.

include_dirs, if given, must be a list of strings, the directories to add to the default include file search path for this compilation only.

depends, if given, must be a list of strings, the directories to add to the default include file search path for this compilation only.

dependencies, if given, is a list of filenames that all targets depend on. If a source file is older than any file in depends, then the source file will be recompiled. This supports dependency tracking, but only at a coarse granularity.

Raises CompileError on failure.

create_static_lib(objects, output_libname[, output_dir=None, debug=0, target_lang=None])
Link a bunch of stuff together to create a static library file. The “bunch of stuff” consists of the list of object files supplied as objects, the extra object files supplied to add_link_object()
and/or \texttt{set\_link\_objects()}, the libraries supplied to \texttt{add\_library()} and/or \texttt{set\_libraries()}, and the libraries supplied as \texttt{libraries} (if any).

\textit{output\_libname} should be a library name, not a filename; the filename will be inferred from the library name. \textit{output\_dir} is the directory where the library file will be put.

\textit{debug} is a boolean; if true, debugging information will be included in the library (note that on most platforms, it is the compile step where this matters: the \textit{debug} flag is included here just for consistency).

\textit{target\_lang} is the target language for which the given objects are being compiled. This allows specific linkage time treatment of certain languages.

Raises \texttt{LibError} on failure.

\texttt{link()}:

\begin{verbatim}
link(target_desc, objects, output_filename[, output_dir=None, libraries=None, library_dirs=None, runtime_library_dirs=None, export_symbols=None, debug=0, extra_preargs=None, extra_postargs=None, build_temp=None, target_lang=None ])
\end{verbatim}

Link a bunch of stuff together to create an executable or shared library file.

The “bunch of stuff” consists of the list of object files supplied as \textit{objects}. \textit{output\_filename} should be a filename. If \textit{output\_dir} is supplied, \textit{output\_filename} is relative to it (i.e. \textit{output\_filename} can provide directory components if needed).

\textit{libraries} is a list of libraries to link against. These are library names, not filenames, since they’re translated into filenames in a platform-specific way (eg. \texttt{foo} becomes \texttt{libfoo.a} on Unix and \texttt{foo.lib} on DOS/Windows). However, they can include a directory component, which means the linker will look in that specific directory rather than searching all the normal locations.

\textit{library\_dirs}, if supplied, should be a list of directories to search for libraries that were specified as bare library names (ie. no directory component). These are on top of the system default and those supplied to \texttt{add\_library\_dir()} and/or \texttt{set\_library\_dirs()}. \textit{runtime\_library\_dirs} is a list of directories that will be embedded into the shared library and used to search for other shared libraries that “it” depends on at run-time. (This may only be relevant on Unix.)

\textit{export\_symbols} is a list of symbols that the shared library will export. (This appears to be relevant only on Windows.)

\textit{debug} is as for \texttt{compile()} and \texttt{create\_static\_lib()}, with the slight distinction that it actually matters on most platforms (as opposed to \texttt{create\_static\_lib()}, which includes a \textit{debug} flag mostly for form’s sake).

\textit{extra\_preargs} and \textit{extra\_postargs} are as for \texttt{compile()} (except of course that they supply command-line arguments for the particular linker being used).

\textit{target\_lang} is the target language for which the given objects are being compiled. This allows specific linkage time treatment of certain languages.

 Raises \texttt{LinkError} on failure.

\texttt{link\_executable()}:

\begin{verbatim}
link\_executable(objects, output\_progname[, output\_dir=None, libraries=None, library\_dirs=None, runtime\_library\_dirs=None, debug=0, extra\_preargs=None, extra\_postargs=None, build\_temp=None, target\_lang=None ])
\end{verbatim}

Link an executable. \textit{output\_progname} is the name of the file executable, while \textit{objects} is a list of object filenames to link in. Other arguments are as for the \texttt{link()} method.

\texttt{link\_shared\_lib()}:

\begin{verbatim}
link\_shared\_lib(objects, output\_libname[, output\_dir=None, libraries=None, library\_dirs=None, runtime\_library\_dirs=None, export\_symbols=None, debug=0, extra\_preargs=None, extra\_postargs=None, build\_temp=None, target\_lang=None ])
\end{verbatim}

Link a shared library. \textit{output\_libname} is the name of the output library, while \textit{objects} is a list of object filenames to link in. Other arguments are as for the \texttt{link()} method.

\texttt{link\_shared\_object()}:

\begin{verbatim}
link\_shared\_object(objects, output\_filename[, output\_dir=None, libraries=None, library\_dirs=None, runtime\_library\_dirs=None, export\_symbols=None, debug=0, extra\_preargs=None, extra\_postargs=None, build\_temp=None, target\_lang=None ])
\end{verbatim}
**Distributing Python Modules, Release 3.3.3**

Distribute a shared object. *output_filename* is the name of the shared object that will be created, while *objects* is a list of object filenames to link in. Other arguments are as for the *link()* method.

```python
preprocess(source[, output_file=None, macros=None, include_dirs=None, extra_preargs=None, extra_postargs=None])
```

Preprocess a single C/C++ source file, named in *source*. Output will be written to file named *output_file*, or *stdout* if *output_file* not supplied. *macros* is a list of macro definitions as for *compile()* which will augment the macros set with *define_macro()* and *undefine_macro()*.

*include_dirs* is a list of directory names that will be added to the default list, in the same way as *add_include_dir()*.

Raisies *PreprocessError* on failure.

The following utility methods are defined by the *CCompiler* class, for use by the various concrete subclasses.

```python
executable_filename(basename[, strip_dir=0, output_dir=''])
```

Returns the filename of the executable for the given *basename*. Typically for non-Windows platforms this is the same as the basename, while Windows will get a .exe added.

```python
library_filename(libname[, lib_type='static', strip_dir=0, output_dir=''])
```

Returns the filename for the given library name on the current platform. On Unix a library with *lib_type* of ’static’ will typically be of the form liblibname.a, while a *lib_type* of ’dynamic’ will be of the form liblibname.so.

```python
object_filenames(source_filenames[, strip_dir=0, output_dir=''])
```

Returns the name of the object files for the given source files. *source_filenames* should be a list of filenames.

```python
shared_object_filename(basename[, strip_dir=0, output_dir=''])
```

Returns the name of a shared object file for the given file name *basename*.

```python
execute(func, args[, msg=None, level=1])
```

Invokes distutils.util.execute(). This method invokes a Python function *func* with the given arguments *args*, after logging and taking into account the *dry_run* flag.

```python
spawn(cmd)
```

Invokes distutils.util.spawn(). This invokes an external process to run the given command.

```python
makedirs(name[, mode=511])
```

Invokes distutils.dir_util.makedirs(). This creates a directory and any missing ancestor directories.

```python
move_file(src, dst)
```

Invokes distutils.file_util.move_file(). Renames *src* to *dst*.

```python
announce(msg[, level=1])
```

Write a message using distutils.log.debug().

```python
warn(msg)
```

Write a warning message *msg* to standard error.

```python
debug_print(msg)
```

If the *debug* flag is set on this *CCompiler* instance, print *msg* to standard output, otherwise do nothing.

**10.3 distutils.unixccompiler — Unix C Compiler**

This module provides the *UnixCCompiler* class, a subclass of *CCompiler* that handles the typical Unix-style command-line C compiler:

- macros defined with `-Dname[=value]`
- macros undefined with `-Uname`

---

10.3. distutils.unixccompiler — Unix C Compiler 51
• include search directories specified with -Idir
• libraries specified with -llib
• library search directories specified with -Ldir
• compile handled by cc (or similar) executable with -c option: compiles .c to .o
• link static library handled by ar command (possibly with ranlib)
• link shared library handled by cc -shared

10.4 distutils.msvccompiler — Microsoft Compiler

This module provides MSVCCompiler, an implementation of the abstract CCompiler class for Microsoft Visual Studio. Typically, extension modules need to be compiled with the same compiler that was used to compile Python. For Python 2.3 and earlier, the compiler was Visual Studio 6. For Python 2.4 and 2.5, the compiler is Visual Studio .NET 2003. The AMD64 and Itanium binaries are created using the Platform SDK.

MSVCCompiler will normally choose the right compiler, linker etc. on its own. To override this choice, the environment variables DISTUTILS_USE_SDK and MSSdk must be both set. MSSdk indicates that the current environment has been setup by the SDK’s SetEnv.Cmd script, or that the environment variables had been registered when the SDK was installed; DISTUTILS_USE_SDK indicates that the distutils user has made an explicit choice to override the compiler selection by MSVCCompiler.

10.5 distutils.bcppcompiler — Borland Compiler

This module provides BorlandCCompiler, an subclass of the abstract CCompiler class for the Borland C++ compiler.

10.6 distutils.cygwincompiler — Cygwin Compiler

This module provides the CygwinCCompiler class, a subclass of UnixCCompiler that handles the Cygwin port of the GNU C compiler to Windows. It also contains the Mingw32CCompiler class which handles the mingw32 port of GCC (same as cygwin in no-cygwin mode).

10.7 distutils.emxccompiler — OS/2 EMX Compiler

This module provides the EMXCCompiler class, a subclass of UnixCCompiler that handles the EMX port of the GNU C compiler to OS/2.

10.8 distutils.archive_util — Archiving utilities

This module provides a few functions for creating archive files, such as tarballs or zipfiles.

distutils.archive_util.make_archive(base_name, format[, root_dir=None, base_dir=None, verbose=0, dry_run=0])

Create an archive file (eg. zip or tar). base_name is the name of the file to create, minus any format-specific extension; format is the archive format: one of zip, tar, ztar, or gztar. root_dir is a directory that will be the root directory of the archive; ie. we typically chdir into root_dir before creating the archive. base_dir is the directory where we start archiving from; ie. base_dir will be the common prefix of all files and directories in the archive. root_dir and base_dir both default to the current directory. Returns the name of the archive file.
distutils.archive_util.make_tarball(base_name, base_dir[, compress='gzip', verbose=0, dry_run=0])

‘Create an (optional compressed) archive as a tar file from all files in and under base_dir. The output tar file will be named base_dir.tar, possibly plus the appropriate compression extension (.gz, .bz2 or .2). Return the output filename.

distutils.archive_util.make_zipfile(base_name, base_dir[, verbose=0, dry_run=0])

Create a zip file from all files in and under base_dir. The output zip file will be named base_name+.zip. Uses either the zipfile Python module (if available) or the InfoZIP zip utility (if installed and found on the default search path). If neither tool is available, raises DistutilsExecError. Returns the name of the output zip file.

10.9 distutils.dep_util — Dependency checking

This module provides functions for performing simple, timestamp-based dependency of files and groups of files; also, functions based entirely on such timestamp dependency analysis.

distutils.dep_util.newer(source, target)

Return true if source exists and is more recently modified than target, or if source exists and target doesn’t. Return false if both exist and target is the same age or newer than source. Raise DistutilsFileError if source does not exist.

distutils.dep_util.newer_pairwise(sources, targets)

Walk two filename lists in parallel, testing if each source is newer than its corresponding target. Return a pair of lists (sources, targets) where source is newer than target, according to the semantics of newer().

distutils.dep_util.newer_group(sources, target[, missing='error'])

Return true if target is out-of-date with respect to any file listed in sources. In other words, if target exists and is newer than every file in sources, return false; otherwise return true. missing controls what we do when a source file is missing; the default (‘error’) is to blow up with an OSError from inside os.stat(); if it is ‘ignore’, we silently drop any missing source files; if it is ‘newer’, any missing source files make us assume that target is out-of-date (this is handy in “dry-run” mode: it’ll make you pretend to carry out commands that wouldn’t work because inputs are missing, but that doesn’t matter because you’re not actually going to run the commands).

10.10 distutils.dir_util — Directory tree operations

This module provides functions for operating on directories and trees of directories.

distutils.dir_util.mkpath(name[, mode=0o777, verbose=0, dry_run=0])

Create a directory and any missing ancestor directories. If the directory already exists (or if name is the empty string, which means the current directory, which of course exists), then do nothing. Raise DistutilsFileError if unable to create some directory along the way (eg. some sub-path exists, but is a file rather than a directory). If verbose is true, print a one-line summary of each mkdir to stdout. Return the list of directories actually created.

distutils.dir_util.create_tree(base_dir, files[, mode=0o777, verbose=0, dry_run=0])

Create all the empty directories under base_dir needed to put files there. base_dir is just the name of a directory which doesn’t necessarily exist yet; files is a list of filenames to be interpreted relative to base_dir. base_dir + the directory portion of every file in files will be created if it doesn’t already exist. mode, verbose and dry_run flags are as for mkpath().

distutils.dir_util.copy_tree(src, dst[, preserve_mode=1, preserve_times=1, preserve_symlinks=0, update=0, verbose=0, dry_run=0])

Copy an entire directory tree src to a new location dst. Both src and dst must be directory names. If src is not a directory, raise DistutilsFileError. If dst does not exist, it is created with mkpath(). The end result of the copy is that every file in src is copied to dst, and directories under src are recursively copied
to dst. Return the list of files that were copied or might have been copied, using their output name. The return value is unaffected by update or dry_run: it is simply the list of all files under src, with the names changed to be under dst.

preserve_mode and preserve_times are the same as for distutils.file_util.copy_file(): note that they only apply to regular files, not to directories. If preserve_symlinks is true, symlinks will be copied as symlinks (on platforms that support them!); otherwise (the default), the destination of the symlink will be copied. update and verbose are the same as for copy_file().

Files in src that begin with .nfs are skipped (more information on these files is available in answer D2 of the NFS FAQ page. Changed in version 3.3.1: NFS files are ignored.

distutils.dir_util.remove_tree(directory[, verbose=0, dry_run=0])
Recursively remove directory and all files and directories underneath it. Any errors are ignored (apart from being reported to sys.stdout if verbose is true).

10.11 distutils.file_util — Single file operations

This module contains some utility functions for operating on individual files.

distutils.file_util.copy_file(src, dst[, preserve_mode=1, preserve_times=1, update=0, 
 link=None, verbose=0, dry_run=0])
Copy file src to dst. If dst is a directory, then src is copied there with the same name; otherwise, it must be a filename. (If the file exists, it will be ruthlessly clobbered.) If preserve_mode is true (the default), the file’s mode (type and permission bits, or whatever is analogous on the current platform) is copied. If preserve_times is true (the default), the last-modified and last-access times are copied as well. If update is true, src will only be copied if dst does not exist, or if dst does exist but is older than src.

link allows you to make hard links (using os.link()) or symbolic links (using os.symlink()) instead of copying: set it to ‘hard’ or ‘sym’; if it is None (the default), files are copied. Don’t set link on systems that don’t support it: copy_file() doesn’t check if hard or symbolic linking is available. It uses _copy_file_contents() to copy file contents.

Return a tuple (dest_name, copied): dest_name is the actual name of the output file, and copied is true if the file was copied (or would have been copied, if dry_run true).

distutils.file_util.move_file(src, dst[, verbose, dry_run])
Move file src to dst. If dst is a directory, the file will be moved into it with the same name; otherwise, src is just renamed to dst. Returns the new full name of the file.

Warning: Handles cross-device moves on Unix using copy_file(). What about other systems?

distutils.file_util.write_file(filename, contents)
Create a file called filename and write contents (a sequence of strings without line terminators) to it.

10.12 distutils.util — Miscellaneous other utility functions

This module contains other assorted bits and pieces that don’t fit into any other utility module.

distutils.util.get_platform()
Return a string that identifies the current platform. This is used mainly to distinguish platform-specific build directories and platform-specific built distributions. Typically includes the OS name and version and the architecture (as supplied by ‘os.uname()’), although the exact information included depends on the OS; eg. for IRIX the architecture isn’t particularly important (IRIX only runs on SGI hardware), but for Linux the kernel version isn’t particularly important.

Examples of returned values:

• linux-i586
For non-POSIX platforms, currently just returns `sys.platform`.

For Mac OS X systems the OS version reflects the minimal version on which binaries will run (that is, the value of `MACOSX_DEPLOYMENT_TARGET` during the build of Python), not the OS version of the current system.

For universal binary builds on Mac OS X the architecture value reflects the universal binary status instead of the architecture of the current processor. For 32-bit universal binaries the architecture is `fat`, for 64-bit universal binaries the architecture is `fat64`, and for 4-way universal binaries the architecture is `universal`. Starting from Python 2.7 and Python 3.2 the architecture `fat3` is used for a 3-way universal build (ppc, i386, x86_64) and `intel` is used for a universal build with the i386 and x86_64 architectures.

Examples of returned values on Mac OS X:

- `macosx-10.3-ppc`
- `macosx-10.3-fat`
- `macosx-10.5-universal`
- `macosx-10.6-intel`

```
distutils.util.convert_path(pathname)
```

Return `pathname` as a name that will work on the native filesystem, i.e. split it on ‘/’ and put it back together again using the current directory separator. Needed because filenames in the setup script are always supplied in Unix style, and have to be converted to the local convention before we can actually use them in the filesystem. Raises `ValueError` on non-Unix-ish systems if `pathname` either starts or ends with a slash.

```
distutils.util.change_root(new_root, pathname)
```

Return `pathname` with `new_root` prepended. If `pathname` is relative, this is equivalent to `os.path.join(new_root, pathname)` Otherwise, it requires making `pathname` relative and then joining the two, which is tricky on DOS/Windows.

```
distutils.util.check_environ()
```

Ensure that ‘os.environ’ has all the environment variables we guarantee that users can use in config files, command-line options, etc. Currently this includes:

- `HOME` - user’s home directory (Unix only)
- `PLAT` - description of the current platform, including hardware and OS (see `get_platform()`)

```
distutils.util.subst_vars(s, local_vars)
```

Perform shell/Perl-style variable substitution on `s`. Every occurrence of `$` followed by a name is considered a variable, and variable is substituted by the value found in the `local_vars` dictionary, or in `os.environ` if it’s not in `local_vars`. `os.environ` is first checked/augmented to guarantee that it contains certain values: see `check_environ()`. Raise `ValueError` for any variables not found in either `local_vars` or `os.environ`.

Note that this is not a fully-fledged string interpolation function. A valid `$variable` can consist only of upper and lower case letters, numbers and an underscore. No { } or ( ) style quoting is available.

```
distutils.util.grok_environment_error(exc, prefix='error: ')
```

Generate a useful error message from an `OSError` exception object. Handles Python 1.5.1 and later styles, and does what it can to deal with exception objects that don’t have a filename (which happens when the error is due to a two-file operation, such as `rename()` or `link()`). Returns the error message as a string prefixed with `prefix`.

```
distutils.util.split_quoted(s)
```

Split a string up according to Unix shell-like rules for quotes and backslashes. In short: words are delimited
by spaces, as long as those spaces are not escaped by a backslash, or inside a quoted string. Single and
double quotes are equivalent, and the quote characters can be backslash-escaped. The backslash is stripped
from any two-character escape sequence, leaving only the escaped character. The quote characters are
stripped from any quoted string. Returns a list of words.

```python
distutils.util.execute (func, args[, msg=None, verbose=0, dry_run=0])
```
Perform some action that affects the outside world (for instance, writing to the filesystem). Such actions are
special because they are disabled by the dry_run flag. This method takes care of all that bureaucracy for
you; all you have to do is supply the function to call and an argument tuple for it (to embody the “external
action” being performed), and an optional message to print.

```python
distutils.util.strtobool (val)
```
Convert a string representation of truth to true (1) or false (0).

- True values are y, yes, t, true, on and 1; false values are n, no, f, false, off and 0. Raises
  ValueError if val is anything else.

```python
distutils.util.byte_compile (py_files[, optimize=0, force=0, prefix=None, base_dir=None,
  verbose=1, dry_run=0, direct=None])
```
Byte-compile a collection of Python source files to either .pyc or .pyo files in a __pycache__ sub-
directory (see PEP 3147). py_files is a list of files to compile; any files that don’t end in .py are silently
skipped. optimize must be one of the following:

- 0 - don’t optimize (generate .pyc)
- 1 - normal optimization (like python -O)
- 2 - extra optimization (like python -OO)

If force is true, all files are recompiled regardless of timestamps.

The source filename encoded in each bytecode file defaults to the filenames listed in py_files; you can
modify these with prefix and basedir. prefix is a string that will be stripped off of each source filename, and
base_dir is a directory name that will be prepended (after prefix is stripped). You can supply either or both
(or neither) of prefix and base_dir, as you wish.

If dry_run is true, doesn’t actually do anything that would affect the filesystem.

Byte-compilation is either done directly in this interpreter process with the standard py_compile module,
or indirectly by writing a temporary script and executing it. Normally, you should let byte_compile() figure out to use direct compilation or not (see the source for details). The direct flag is used by the script
generated in indirect mode; unless you know what you’re doing, leave it set to None. Changed in version
3.2.3: Create .pyc or .pyo files with an import magic tag in their name, in a __pycache__ subdirectory instead of files without tag in the current directory.

```python
distutils.util.rfc822_escape (header)
```
Return a version of header escaped for inclusion in an RFC 822 header, by ensuring there are 8 spaces
space after each newline. Note that it does no other modification of the string.

## 10.13 distutils.dist — The Distribution class

This module provides the Distribution class, which represents the module distribution being
built/installed/distributed.

## 10.14 distutils.extension — The Extension class

This module provides the Extension class, used to describe C/C++ extension modules in setup scripts.
10.15 distutils.debug — Distutils debug mode

This module provides the DEBUG flag.

10.16 distutils.errors — Distutils exceptions

Provides exceptions used by the Distutils modules. Note that Distutils modules may raise standard exceptions; in particular, SystemExit is usually raised for errors that are obviously the end-user’s fault (e.g., bad command-line arguments).

This module is safe to use in from ... import * mode; it only exports symbols whose names start with Distutils and end with Error.

10.17 distutils.fancy_getopt — Wrapper around the standard getopt module

This module provides a wrapper around the standard getopt module that provides the following additional features:

- short and long options are tied together
- options have help strings, so fancy_getopt() could potentially create a complete usage summary
- options set attributes of a passed-in object
- boolean options can have “negative aliases” — e.g., if --quiet is the “negative alias” of --verbose, then --quiet on the command line sets verbose to false.

Distutils.fancy_getopt.fancy_getopt(options, negative_opt, object, args)
Wrapper function. options is a list of (long_option, short_option, help_string) 3-tuples as described in the constructor for FancyGetopt. negative_opt should be a dictionary mapping option names to option names, both the key and value should be in the options list. object is an object which will be used to store values (see the getopt() method of the FancyGetopt class). args is the argument list. Will use sys.argv[1:] if you pass None as args.

Distutils.fancy_getopt.wrap_text(text, width)
Wraps text to less than width wide.

class distutils.fancy_getopt.FancyGetopt([option_table=None])
The option_table is a list of 3-tuples: (long_option, short_option, help_string)
If an option takes an argument, its long_option should have '=' appended; short_option should just be a single character, no ':' in any case. short_option should be None if a long_option doesn’t have a corresponding short_option. All option tuples must have long options.

The FancyGetopt class provides the following methods:

FancyGetopt.getopt([args=None, object=None])
Parse command-line options in args. Store as attributes on object.
If args is None or not supplied, uses sys.argv[1:]. If object is None or not supplied, creates a new OptionDummy instance, stores option values there, and returns a tuple (args, object). If object is supplied, it is modified in place and getopt() just returns args; in both cases, the returned args is a modified copy of the passed-in args list, which is left untouched.

FancyGetopt.get_option_order()
Returns the list of (option, value) tuples processed by the previous run of getopt() Raises RuntimeError if getopt() hasn’t been called yet.
FancyGetopt.generate_help([header=None])

Generate help text (a list of strings, one per suggested line of output) from the option table for this FancyGetopt object.

If supplied, prints the supplied header at the top of the help.

10.18 distutils.filelist — The FileList class

This module provides the FileList class, used for poking about the filesystem and building lists of files.

10.19 distutils.log — Simple PEP 282-style logging

10.20 distutils.spawn — Spawn a sub-process

This module provides the spawn() function, a front-end to various platform-specific functions for launching another program in a sub-process. Also provides find_executable() to search the path for a given executable name.

10.21 distutils.sysconfig — System configuration information

The distutils.sysconfig module provides access to Python’s low-level configuration information. The specific configuration variables available depend heavily on the platform and configuration. The specific variables depend on the build process for the specific version of Python being run; the variables are those found in the Makefile and configuration header that are installed with Python on Unix systems. The configuration header is called pyconfig.h for Python versions starting with 2.2, and config.h for earlier versions of Python.

Some additional functions are provided which perform some useful manipulations for other parts of the distutils package.

distutils.sysconfig.PREFIX
    The result of os.path.normpath(sys.prefix).

distutils.sysconfig.EXEC_PREFIX
    The result of os.path.normpath(sys.exec_prefix).

distutils.sysconfig.get_config_var(name)
    Return the value of a single variable. This is equivalent to get_config_vars().get(name).

distutils.sysconfig.get_config_vars(...)
    Return a set of variable definitions. If there are no arguments, this returns a dictionary mapping names of configuration variables to values. If arguments are provided, they should be strings, and the return value will be a sequence giving the associated values. If a given name does not have a corresponding value, None will be included for that variable.

distutils.sysconfig.get_config_h_filename()
    Return the full path name of the configuration header. For Unix, this will be the header generated by the configure script; for other platforms the header will have been supplied directly by the Python source distribution. The file is a platform-specific text file.

distutils.sysconfig.get_makefile_filename()
    Return the full path name of the Makefile used to build Python. For Unix, this will be a file generated by the configure script; the meaning for other platforms will vary. The file is a platform-specific text file, if it exists. This function is only useful on POSIX platforms.
distutils.sysconfig.get_python_inc([plat_specific[, prefix ]])

Return the directory for either the general or platform-dependent C include files. If plat_specific is true, the
platform-dependent include directory is returned; if false or omitted, the platform-independent directory is
returned. If prefix is given, it is used as either the prefix instead of PREFIX, or as the exec-prefix instead of
EXEC_PREFIX if plat_specific is true.

distutils.sysconfig.get_python_lib([plat_specific[, standard_lib[, prefix ]]])

Return the directory for either the general or platform-dependent library installation. If plat_specific is true, the
platform-dependent include directory is returned; if false or omitted, the platform-independent directory is
returned. If prefix is given, it is used as either the prefix instead of PREFIX, or as the exec-prefix instead of
EXEC_PREFIX if plat_specific is true. If standard_lib is true, the directory for the standard library is
returned rather than the directory for the installation of third-party extensions.

The following function is only intended for use within the distutils package.

distutils.sysconfig.customize_compiler(compiler)

Do any platform-specific customization of a distutils.ccompiler.CCompiler instance.

This function is only needed on Unix at this time, but should be called consistently to support forward-
compatibility. It inserts the information that varies across Unix flavors and is stored in Python's Makefile.
This information includes the selected compiler, compiler and linker options, and the extension used by the
linker for shared objects.

This function is even more special-purpose, and should only be used from Python's own build procedures.

distutils.sysconfig.set_python_build()

Inform the distutils.sysconfig module that it is being used as part of the build process for Python.
This changes a lot of relative locations for files, allowing them to be located in the build area rather than in
an installed Python.

10.22 distutils.text_file — The TextFile class

This module provides the TextFile class, which gives an interface to text files that (optionally) takes care of
stripping comments, ignoring blank lines, and joining lines with backslashes.

class distutils.text_file.TextFile([filename=None, file=None, **options])

This class provides a file-like object that takes care of all the things you commonly want to do when process-
ing a text file that has some line-by-line syntax: strip comments (as long as # is your comment character),
skip blank lines, join adjacent lines by escaping the newline (ie. backslash at end of line), strip leading
and/or trailing whitespace. All of these are optional and independently controllable.

The class provides a warn() method so you can generate warning messages that report physical line
number, even if the logical line in question spans multiple physical lines. Also provides unreadline() for
implementing line-at-a-time lookahead.

TextFile instances are create with either filename, file, or both. RuntimeError is raised if both are
None. filename should be a string, and file a file object (or something that provides readline() and
close() methods). It is recommended that you supply at least filename, so that TextFile can include it
in warning messages. If file is not supplied, TextFile creates its own using the open() built-in function.

The options are all boolean, and affect the values returned by readline()
<table>
<thead>
<tr>
<th>option name</th>
<th>description</th>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>strip_comments</td>
<td>strip from <code>'#' to end-of-line, as well as any whitespace leading up to the </code>'#'—unless it is escaped by a backslash</td>
<td>true</td>
</tr>
<tr>
<td>lstrip_ws</td>
<td>strip leading whitespace from each line before returning it</td>
<td>false</td>
</tr>
<tr>
<td>rstrip_ws</td>
<td>strip trailing whitespace (including line terminator!) from each line before returning it.</td>
<td>true</td>
</tr>
<tr>
<td>skip_blanks</td>
<td>skip lines that are empty after stripping comments and whitespace. (If both lstrip_ws and rstrip_ws are false, then some lines may consist of solely whitespace: these will not be skipped, even if skip_blanks is true.)</td>
<td>true</td>
</tr>
<tr>
<td>join_lines</td>
<td>if a backslash is the last non-newline character on a line after stripping comments and whitespace, join the following line to it to form one logical line; if N consecutive lines end with a backslash, then N+1 physical lines will be joined to form one logical line.</td>
<td>false</td>
</tr>
<tr>
<td>collapse_join</td>
<td>strip leading whitespace from lines that are joined to their predecessor; only matters if (join_lines and not lstrip_ws)</td>
<td>false</td>
</tr>
</tbody>
</table>

Note that since rstrip_ws can strip the trailing newline, the semantics of readline() must differ from those of the built-in file object’s readline() method! In particular, readline() returns None for end-of-file: an empty string might just be a blank line (or an all-whitespace line), if rstrip_ws is true but skip_blanks is not.

**open**(filename)

Open a new file filename. This overrides any file or filename constructor arguments.

**close()**

Close the current file and forget everything we know about it (including the filename and the current line number).

**warn**(msg[, line=None])

Print (to stderr) a warning message tied to the current logical line in the current file. If the current logical line in the file spans multiple physical lines, the warning refers to the whole range, such as "lines 3–5". If line is supplied, it overrides the current line number; it may be a list or tuple to indicate a range of physical lines, or an integer for a single physical line.

**readline()**

Read and return a single logical line from the current file (or from an internal buffer if lines have previously been “unread” with unreadline()). If the join_lines option is true, this may involve reading multiple physical lines concatenated into a single string. Updates the current line number, so calling warn() after readline() emits a warning about the physical line(s) just read. Returns None on end-of-file, since the empty string can occur if rstrip_ws is true but skip_blanks is not.

**readlines()**

Read and return the list of all logical lines remaining in the current file. This updates the current line number to the last line of the file.

**unreadline**(line)

Push line (a string) onto an internal buffer that will be checked by future readline() calls. Handy for implementing a parser with line-at-a-time lookahead. Note that lines that are “unread” with unreadline() are not subsequently re-cleansed (whitespace stripped, or whatever) when read with readline(). If multiple calls are made to unreadline() before a call to readline(), the lines will be returned most in most recent first order.

### 10.23 distutils.version — Version number classes

### 10.24 distutils.cmd — Abstract base class for Distutils commands

This module supplies the abstract base class Command.
class distutils.cmd.Command(dist)

Abstract base class for defining command classes, the “worker bees” of the Distutils. A useful analogy for command classes is to think of them as subroutines with local variables called options. The options are declared in initialize_options() and defined (given their final values) in finalize_options(), both of which must be defined by every command class. The distinction between the two is necessary because option values might come from the outside world (command line, config file, ...), and any options dependent on other options must be computed after these outside influences have been processed — hence finalize_options(). The body of the subroutine, where it does all its work based on the values of its options, is the run() method, which must also be implemented by every command class.

The class constructor takes a single argument dist, a Distribution instance.

10.25 Creating a new Distutils command

This section outlines the steps to create a new Distutils command.

A new command lives in a module in the distutils.command package. There is a sample template in that directory called command_template. Copy this file to a new module with the same name as the new command you’re implementing. This module should implement a class with the same name as the module (and the command). So, for instance, to create the command peel_banana (so that users can run setup.py peel_banana), you’d copy command_template to distutils/command/peel_banana.py, then edit it so that it’s implementing the class peel_banana, a subclass of distutils.cmd.Command.

Subclasses of Command must define the following methods.

Command.initialize_options()

Set default values for all the options that this command supports. Note that these defaults may be overridden by other commands, by the setup script, by config files, or by the command-line. Thus, this is not the place to code dependencies between options; generally, initialize_options() implementations are just a bunch of self.foo = None assignments.

Command.finalize_options()

Set final values for all the options that this command supports. This is always called as late as possible, i.e., after any option assignments from the command-line or from other commands have been done. Thus, this is the place to code option dependencies: if foo depends on bar, then it is safe to set foo from bar as long as foo still has the same value it was assigned in initialize_options().

Command.run()

A command’s raison d’etre: carry out the action it exists to perform, controlled by the options initialized in initialize_options(), customized by other commands, the setup script, the command-line, and config files, and finalized in finalize_options(). All terminal output and filesystem interaction should be done by run().

Command.sub_commands

sub_commands formalizes the notion of a “family” of commands, e.g. install as the parent with subcommands install_lib, install_headers, etc. The parent of a family of commands defines sub_commands as a class attribute; it’s a list of 2-tuples (command_name, predicate), with command_name a string and predicate a function, a string or None. predicate is a method of the parent command that determines whether the corresponding command is applicable in the current situation. (E.g. install_headers is only applicable if we have any C header files to install.) If predicate is None, that command is always applicable.

sub_commands is usually defined at the end of a class, because predicates can be methods of the class, so they must already have been defined. The canonical example is the install command.
10.26 distutils.command — Individual Distutils commands

10.27 distutils.command.bdist — Build a binary installer

10.28 distutils.command.bdist_packager — Abstract base class for packagers

10.29 distutils.command.bdist_dumb — Build a “dumb” installer

10.30 distutils.command.bdist_msi — Build a Microsoft Installer binary package

```python
class distutils.command.bdist_msi.bdist_msi
    Builds a Windows Installer (.msi) binary package.

    In most cases, the bdist_msi installer is a better choice than the bdist_wininst installer, because it provides better support for Win64 platforms, allows administrators to perform non-interactive installations, and allows installation through group policies.
```

10.31 distutils.command.bdist_rpm — Build a binary distribution as a Redhat RPM and SRPM

10.32 distutils.command.bdist_wininst — Build a Windows installer

10.33 distutils.command.sdist — Build a source distribution

10.34 distutils.command.build — Build all files of a package

10.35 distutils.command.build_clib — Build any C libraries in a package

10.36 distutils.command.build_ext — Build any extensions in a package

10.37 distutils.command.build_py — Build the .py/.pyc files of a package

```python
class distutils.command.build_py.build_py

class distutils.command.build_py.build_py_2to3
    Alternative implementation of build_py which also runs the 2to3 conversion library on each .py file that is going to be installed. To use this in a setup.py file for a distribution that is designed to run with both Python 2.x and 3.x, add:
```
try:
    from distutils.command.build_py import build_py_2to3 as build_py
except Import Error:
    from distutils.command.build_py import build_py

to your setup.py, and later:

cmdclass = {'build_py': build_py}

to the invocation of setup().

10.38 distutils.command.build_scripts — Build the scripts of a package

10.39 distutils.command.clean — Clean a package build area

10.40 distutils.command.config — Perform package configuration

10.41 distutils.command.install — Install a package

10.42 distutils.command.install_data — Install data files from a package

10.43 distutils.command.install_headers — Install C/C++ header files from a package

10.44 distutils.command.install_lib — Install library files from a package

10.45 distutils.command.install_scripts — Install script files from a package

10.46 distutils.command.register — Register a module with the Python Package Index

The register command registers the package with the Python Package Index. This is described in more detail in PEP 301.

10.47 distutils.command.check — Check the meta-data of a package

The check command performs some tests on the meta-data of a package. For example, it verifies that all required meta-data are provided as the arguments passed to the setup() function.
The default Python prompt of the interactive shell. Often seen for code examples which can be executed interactively in the interpreter.

... The default Python prompt of the interactive shell when entering code for an indented code block or within a pair of matching left and right delimiters (parentheses, square brackets or curly braces).

2to3 A tool that tries to convert Python 2.x code to Python 3.x code by handling most of the incompatibilities which can be detected by parsing the source and traversing the parse tree.

2to3 is available in the standard library as lib2to3; a standalone entry point is provided as Tools/scripts/2to3. See 2to3-reference.

Abstract base classes complement duck-typing by providing a way to define interfaces when other techniques like hasattr() would be clumsy or subtly wrong (for example with magic methods). ABCs introduce virtual subclasses, which are classes that don’t inherit from a class but are still recognized by isinstance() and issubclass(): see the abc module documentation. Python comes with many built-in ABCs for data structures (in the collections.abc module), numbers (in the numbers module), streams (in the io module), import finders and loaders (in the importlib.abc module). You can create your own ABCs with the abc module.

A value passed to a function (or method) when calling the function. There are two types of arguments:

- **keyword argument**: an argument preceded by an identifier (e.g. name=) in a function call or passed as a value in a dictionary preceded by **. For example, 3 and 5 are both keyword arguments in the following calls to complex():

  complex(real=3, imag=5)
  complex(**{'real': 3, 'imag': 5})

- **positional argument**: an argument that is not a keyword argument. Positional arguments can appear at the beginning of an argument list and/or be passed as elements of an iterable preceded by *. For example, 3 and 5 are both positional arguments in the following calls:

  complex(3, 5)
  complex(*(3, 5))

Arguments are assigned to the named local variables in a function body. See the calls section for the rules governing this assignment. Syntactically, any expression can be used to represent an argument; the evaluated value is assigned to the local variable.

See also the parameter glossary entry, the FAQ question on the difference between arguments and parameters, and PEP 362.

A value associated with an object which is referenced by name using dotted expressions. For example, if an object o has an attribute a it would be referenced as o.a.

Benevolent Dictator For Life, a.k.a. Guido van Rossum, Python’s creator.

An object that supports the bufferobjects, like bytes, bytearray or memoryview. Bytes-like objects can be used for various operations that expect binary data, such as compression, saving to a
binary file or sending over a socket. Some operations need the binary data to be mutable, in which case not all bytes-like objects can apply.

**bytecode**  Python source code is compiled into bytecode, the internal representation of a Python program in the CPython interpreter. The bytecode is also cached in `.pyc` and `.pyo` files so that executing the same file is faster the second time (recompilation from source to bytecode can be avoided). This “intermediate language” is said to run on a virtual machine that executes the machine code corresponding to each bytecode. Do note that bytecodes are not expected to work between different Python virtual machines, nor to be stable between Python releases.

A list of bytecode instructions can be found in the documentation for the `dis` module.

**class**  A template for creating user-defined objects. Class definitions normally contain method definitions which operate on instances of the class.

**coercion**  The implicit conversion of an instance of one type to another during an operation which involves two arguments of the same type. For example, `int(3.15)` converts the floating point number to the integer 3, but in `3+4.5`, each argument is of a different type (one int, one float), and both must be converted to the same type before they can be added or it will raise a `TypeError`. Without coercion, all arguments of even compatible types would have to be normalized to the same value by the programmer, e.g., `float(3)+4.5` rather than just `3+4.5`.

**complex number**  An extension of the familiar real number system in which all numbers are expressed as a sum of a real part and an imaginary part. Imaginary numbers are real multiples of the imaginary unit (the square root of $-1$), often written $i$ in mathematics or $j$ in engineering. Python has built-in support for complex numbers, which are written with this latter notation; the imaginary part is written with a $j$ suffix, e.g., $3+1j$. To get access to complex equivalents of the `math` module, use `cmath`. Use of complex numbers is a fairly advanced mathematical feature. If you’re not aware of a need for them, it’s almost certain you can safely ignore them.

**context manager**  An object which controls the environment seen in a `with` statement by defining `__enter__()` and `__exit__()` methods. See PEP 343.

**CPython**  The canonical implementation of the Python programming language, as distributed on python.org. The term “CPython” is used when necessary to distinguish this implementation from others such as Jython or IronPython.

**decorator**  A function returning another function, usually applied as a function transformation using the `@wrapper` syntax. Common examples for decorators are `classmethod()` and `staticmethod()`.

The decorator syntax is merely syntactic sugar, the following two function definitions are semantically equivalent:

```python
def f(...):
...

f = staticmethod(f)

@staticmethod
def f(...):
...
```

The same concept exists for classes, but is less commonly used there. See the documentation for `function definitions` and `class definitions` for more about decorators.

**descriptor**  Any object which defines the methods `__get__()`, `__set__()`, or `__delete__()`. When a class attribute is a descriptor, its special binding behavior is triggered upon attribute lookup. Normally, using `a.b` to get, set or delete an attribute looks up the object named `b` in the class dictionary for `a`, but if `b` is a descriptor, the respective descriptor method gets called. Understanding descriptors is a key to a deep understanding of Python because they are the basis for many features including functions, methods, properties, class methods, static methods, and reference to super classes.

For more information about descriptors’ methods, see `descriptors`.

**dictionary**  An associative array, where arbitrary keys are mapped to values. The keys can be any object with `__hash__()` and `__eq__()` methods. Called a hash in Perl.
docstring  A string literal which appears as the first expression in a class, function or module. While ignored when the suite is executed, it is recognized by the compiler and put into the `__doc__` attribute of the enclosing class, function or module. Since it is available via introspection, it is the canonical place for documentation of the object.

duck-typing  A programming style which does not look at an object’s type to determine if it has the right interface; instead, the method or attribute is simply called or used (“If it looks like a duck and quacks like a duck, it must be a duck.”) By emphasizing interfaces rather than specific types, well-designed code improves its flexibility by allowing polymorphic substitution. Duck-typing avoids tests using `type()` or `isinstance()`. (Note, however, that duck-typing can be complemented with abstract base classes.) Instead, it typically employs `hasattr()` tests or EAFP programming.

EAFP  Easier to ask for forgiveness than permission. This common Python coding style assumes the existence of valid keys or attributes and catches exceptions if the assumption proves false. This clean and fast style is characterized by the presence of many `try` and `except` statements. The technique contrasts with the LBYL style common to many other languages such as C.

expression  A piece of syntax which can be evaluated to some value. In other words, an expression is an accumulation of expression elements like literals, names, attribute access, operators or function calls which all return a value. In contrast to many other languages, not all language constructs are expressions. There are also statements which cannot be used as expressions, such as `if`. Assignments are also statements, not expressions.

extension module  A module written in C or C++, using Python’s C API to interact with the core and with user code.

file object  An object exposing a file-oriented API (with methods such as `read()` or `write()`) to an underlying resource. Depending on the way it was created, a file object can mediate access to a real on-disk file or to another type of storage or communication device (for example standard input/output, in-memory buffers, sockets, pipes, etc.). File objects are also called file-like objects or streams.

There are actually three categories of file objects: raw binary files, buffered binary files and text files. Their interfaces are defined in the `io` module. The canonical way to create a file object is by using the `open()` function.

file-like object  A synonym for `file object`.

finder  An object that tries to find the loader for a module. It must implement either a method named `find_loader()` or a method named `find_module()`.

floor division  Mathematical division that rounds down to nearest integer. The floor division operator is `//`. For example, the expression `11 // 4` evaluates to `2` in contrast to the `2.75` returned by float true division. Note that `(-11) // 4` is `-3` because that is `-2.75` rounded downward. See `PEP 238`.

function  A series of statements which returns some value to a caller. It can also be passed zero or more arguments which may be used in the execution of the body. See also parameter, method, and the function section.

function annotation  An arbitrary metadata value associated with a function parameter or return value. Its syntax is explained in section function. Annotations may be accessed via the `__annotations__` special attribute of a function object.

Python itself does not assign any particular meaning to function annotations. They are intended to be interpreted by third-party libraries or tools. See `PEP 3107`, which describes some of their potential uses.

__future__  A pseudo-module which programmers can use to enable new language features which are not compatible with the current interpreter.

By importing the `__future__` module and evaluating its variables, you can see when a new feature was first added to the language and when it becomes the default:

```python
>>> import __future__
>>> __future__.division
_Feature((2, 2, 0, 'alpha', 2), (3, 0, 0, 'alpha', 0), 8192)
```
Distributing Python Modules, Release 3.3.3

garbage collection  The process of freeing memory when it is not used anymore. Python performs garbage
collection via reference counting and a cyclic garbage collector that is able to detect and break reference
cycles.

generator  A function which returns an iterator. It looks like a normal function except that it contains yield
statements for producing a series a values usable in a for-loop or that can be retrieved one at a time with the
next() function. Each yield temporarily suspends processing, remembering the location execution
state (including local variables and pending try-statements). When the generator resumes, it picks-up where
it left-off (in contrast to functions which start fresh on every invocation).

generator expression  An expression that returns an iterator. It looks like a normal expression followed by a
for expression defining a loop variable, range, and an optional if expression. The combined expression
generates values for an enclosing function:

```python
>>> sum(i*i for i in range(10))  # sum of squares 0, 1, 4, ... 81
285
```

GIL  See global interpreter lock.

global interpreter lock  The mechanism used by the CPython interpreter to assure that only one thread executes
Python bytecode at a time. This simplifies the CPython implementation by making the object model (in-
cluding critical built-in types such as dict) implicitly safe against concurrent access. Locking the entire
interpreter makes it easier for the interpreter to be multi-threaded, at the expense of much of the parallelism
afforded by multi-processor machines.

However, some extension modules, either standard or third-party, are designed so as to release the GIL when
doing computationally-intensive tasks such as compression or hashing. Also, the GIL is always released
when doing I/O.

Past efforts to create a “free-threaded” interpreter (one which locks shared data at a much finer granularity)
have not been successful because performance suffered in the common single-processor case. It is
believed that overcoming this performance issue would make the implementation much more complicated
and therefore costlier to maintain.

hashable  An object is hashable if it has a hash value which never changes during its lifetime (it needs a
__hash__() method, and can be compared to other objects (it needs an __eq__() method). Hash-
able objects which compare equal must have the same hash value.

Hashability makes an object usable as a dictionary key and a set member, because these data structures use
the hash value internally.

All of Python’s immutable built-in objects are hashable, while no mutable containers (such as lists or dic-
tionsaries) are. Objects which are instances of user-defined classes are hashable by default; they all compare
unequal (except with themselves), and their hash value is their id().

IDLE  An Integrated Development Environment for Python. IDLE is a basic editor and interpreter environment
which ships with the standard distribution of Python.

immutable  An object with a fixed value. Immutable objects include numbers, strings and tuples. Such an object
cannot be altered. A new object has to be created if a different value has to be stored. They play an important
role in places where a constant hash value is needed, for example as a key in a dictionary.

import path  A list of locations (or path entries) that are searched by the path based finder for modules to import.
During import, this list of locations usually comes from sys.path, but for subpackages it may also come
from the parent package’s __path__ attribute.

importing  The process by which Python code in one module is made available to Python code in another module.

importer  An object that both finds and loads a module; both a finder and loader object.

interactive  Python has an interactive interpreter which means you can enter statements and expressions at the
interpreter prompt, immediately execute them and see their results. Just launch python with no arguments
(possibly by selecting it from your computer’s main menu). It is a very powerful way to test out new ideas
or inspect modules and packages (remember help(x)).

interpreted  Python is an interpreted language, as opposed to a compiled one, though the distinction can be
blurry because of the presence of the bytecode compiler. This means that source files can be run directly
without explicitly creating an executable which is then run. Interpreted languages typically have a shorter development/debug cycle than compiled ones, though their programs generally also run more slowly. See also interactive.

**iterable** An object capable of returning its members one at a time. Examples of iterables include all sequence types (such as list, str, and tuple) and some non-sequence types like dict. file objects, and objects of any classes you define with an __iter__() or __getitem__() method. Iterables can be used in a for loop and in many other places where a sequence is needed (zip(), map(), ...). When an iterable object is passed as an argument to the built-in function iter(), it returns an iterator for the object. This iterator is good for one pass over the set of values. When using iterables, it is usually not necessary to call iter() or deal with iterator objects yourself. The for statement does that automatically for you, creating a temporary unnamed variable to hold the iterator for the duration of the loop. See also iterator, sequence, and generator.

**iterator** An object representing a stream of data. Repeated calls to the iterator’s __next__() method (or passing it to the built-in function next()) return successive items in the stream. When no more data are available a StopIteration exception is raised instead. At this point, the iterator object is exhausted and any further calls to its __next__() method just raise StopIteration again. Iterators are required to have an __iter__() method that returns the iterator object itself so every iterator is also iterable and may be used in most places where other iterables are accepted. One notable exception is code which attempts multiple iteration passes. A container object (such as a list) produces a fresh new iterator each time you pass it to the iter() function or use it in a for loop. Attempting this with an iterator will just return the same exhausted iterator object used in the previous iteration pass, making it appear like an empty container.

More information can be found in typeiter.

**key function** A key function or collation function is a callable that returns a value used for sorting or ordering. For example, locale.strxfrm() is used to produce a sort key that is aware of locale specific sort conventions.

A number of tools in Python accept key functions to control how elements are ordered or grouped. They include min(), max(), sorted(), list.sort(), heapq.nsmallest(), heapq.nlargest(), and itertools.groupby().

There are several ways to create a key function. For example, the str.lower() method can serve as a key function for case insensitive sorts. Alternatively, an ad-hoc key function can be built from a lambda expression such as lambda r: (r[0], r[2]). Also, the operator module provides three key function constructors: attrgetter(), itemgetter(), and methodcaller(). See the Sorting HOW TO for examples of how to create and use key functions.

**keyword argument** See argument.

**lambda** An anonymous inline function consisting of a single expression which is evaluated when the function is called. The syntax to create a lambda function is lambda [arguments]: expression

**LBYL** Look before you leap. This coding style explicitly tests for pre-conditions before making calls or lookups. This style contrasts with the EAFP approach and is characterized by the presence of many if statements.

In a multi-threaded environment, the LBYL approach can risk introducing a race condition between “the looking” and “the leaping”. For example, the code, if key in mapping: return mapping[key] can fail if another thread removes key from mapping after the test, but before the lookup. This issue can be solved with locks or by using the EAFP approach.

**list** A built-in Python sequence. Despite its name it is more akin to an array in other languages than to a linked list since access to elements are O(1).

**list comprehension** A compact way to process all or part of the elements in a sequence and return a list with the results. result = [‘{:04x}’ .format(x) for x in range(256) if x % 2 == 0] generates a list of strings containing even hex numbers (0x..) in the range from 0 to 255. The if clause is optional. If omitted, all elements in range(256) are processed.

**loader** An object that loads a module. It must define a method named load_module(). A loader is typically returned by a finder. See PEP 302 for details and importlib.abc.Loader for an abstract base class.
mapping  A container object that supports arbitrary key lookups and implements the methods specified in the Mapping or MutableMapping abstract base classes. Examples include dict, collections.defaultdict, collections.OrderedDict and collections.Counter.

meta path finder  A finder returned by a search of sys.meta_path. Meta path finders are related to, but different from path entry finders.

metaclass  The class of a class. Class definitions create a class name, a class dictionary, and a list of base classes. The metaclass is responsible for taking those three arguments and creating the class. Most object oriented programming languages provide a default implementation. What makes Python special is that it is possible to create custom metaclasses. Most users never need this tool, but when the need arises, metaclasses can provide powerful, elegant solutions. They have been used for logging attribute access, adding thread-safety, tracking object creation, implementing singletons, and many other tasks.

More information can be found in metaclasses.

method  A function which is defined inside a class body. If called as an attribute of an instance of that class, the method will get the instance object as its first argument (which is usually called self). See function and nested scope.

method resolution order  Method Resolution Order is the order in which base classes are searched for a member during lookup. See The Python 2.3 Method Resolution Order.

module  An object that serves as an organizational unit of Python code. Modules have a namespace containing arbitrary Python objects. Modules are loaded into Python by the process of importing.

See also package.

MRO  See method resolution order.

mutable  Mutable objects can change their value but keep their id(). See also immutable.

named tuple  Any tuple-like class whose indexable elements are also accessible using named attributes (for example, time.localtime() returns a tuple-like object where the year is accessible either with an index such as t[0] or with a named attribute like t.tm_year).

A named tuple can be a built-in type such as time.struct_time, or it can be created with a regular class definition. A full featured named tuple can also be created with the factory function collections.namedtuple(). The latter approach automatically provides extra features such as a self-documenting representation like Employee(name='jones', title='programmer').

namespace  The place where a variable is stored. Namespaces are implemented as dictionaries. There are the local, global and built-in namespaces as well as nested namespaces in objects (in methods). Namespaces support modularity by preventing naming conflicts. For instance, the functions builtins.open and os.open() are distinguished by their namespaces. Namespaces also aid readability and maintainability by making it clear which module implements a function. For instance, writing random.seed() or itertools.islice() makes it clear that those functions are implemented by the random and itertools modules, respectively.

namespace package  A PEP 420 package which serves only as a container for subpackages. Namespace packages may have no physical representation, and specifically are not like a regular package because they have no __init__.py file.

See also module.

nested scope  The ability to refer to a variable in an enclosing definition. For instance, a function defined inside another function can refer to variables in the outer function. Note that nested scopes by default work only for reference and not for assignment. Local variables both read and write in the innermost scope. Likewise, global variables read and write to the global namespace. The nonlocal allows writing to outer scopes.

new-style class  Old name for the flavor of classes now used for all class objects. In earlier Python versions, only new-style classes could use Python’s newer, versatile features like __slots__, descriptors, properties, __getattribute__() class methods, and static methods.

object  Any data with state (attributes or value) and defined behavior (methods). Also the ultimate base class of any new-style class.
package  A Python module which can contain submodules or recursively, subpackages. Technically, a package is a Python module with an __path__ attribute.

See also regular package and namespace package.

parameter  A named entity in a function (or method) definition that specifies an argument (or in some cases, arguments) that the function can accept. There are five types of parameters:

- **positional-or-keyword**: specifies an argument that can be passed either **positionally** or as a **keyword argument**. This is the default kind of parameter, for example foo and bar in the following:

  ```python
def func(foo, bar=None): ...
```

- **positional-only**: specifies an argument that can be supplied only by position. Python has no syntax for defining positional-only parameters. However, some built-in functions have positional-only parameters (e.g. abs()).

- **keyword-only**: specifies an argument that can be supplied only by keyword. Keyword-only parameters can be defined by including a single var-positional parameter or bare * in the parameter list of the function definition before them, for example kw_only1 and kw_only2 in the following:

  ```python
def func(arg, *, kw_only1, kw_only2): ...
```

- **var-positional**: specifies that an arbitrary sequence of positional arguments can be provided (in addition to any positional arguments already accepted by other parameters). Such a parameter can be defined by prepending the parameter name with *, for example args in the following:

  ```python
def func(*args, **kwargs): ...
```

- **var-keyword**: specifies that arbitrarily many keyword arguments can be provided (in addition to any keyword arguments already accepted by other parameters). Such a parameter can be defined by prepending the parameter name with **, for example kwargs in the example above.

Parameters can specify both optional and required arguments, as well as default values for some optional arguments.

See also the argument glossary entry, the FAQ question on the difference between arguments and parameters, the inspect.Parameter class, the function section, and PEP 362.

path entry  A single location on the import path which the path based finder consults to find modules for importing.

path entry finder  A finder returned by a callable on sys.path_hooks (i.e. a path entry hook) which knows how to locate modules given a path entry.

path entry hook  A callable on the sys.path_hook list which returns a path entry finder if it knows how to find modules on a specific path entry.

path based finder  One of the default meta path finders which searches an import path for modules.

portion  A set of files in a single directory (possibly stored in a zip file) that contribute to a namespace package, as defined in PEP 420.

positional argument  See argument.

provisional package  A provisional package is one which has been deliberately excluded from the standard library’s backwards compatibility guarantees. While major changes to such packages are not expected, as long as they are marked provisional, backwards incompatible changes (up to and including removal of the package) may occur if deemed necessary by core developers. Such changes will not be made gratuitously – they will occur only if serious flaws are uncovered that were missed prior to the inclusion of the package.

This process allows the standard library to continue to evolve over time, without locking in problematic design errors for extended periods of time. See PEP 411 for more details.

Python 3000  Nickname for the Python 3.x release line (coined long ago when the release of version 3 was something in the distant future.) This is also abbreviated “Py3k”.

Pythonic  An idea or piece of code which closely follows the most common idioms of the Python language, rather than implementing code using concepts common to other languages. For example, a common idiom
in Python is to loop over all elements of an iterable using a `for` statement. Many other languages don’t have this type of construct, so people unfamiliar with Python sometimes use a numerical counter instead:

```python
for i in range(len(food)):
    print(food[i])
```

As opposed to the cleaner, Pythonic method:

```python
for piece in food:
    print(piece)
```

**Qualified name** A dotted name showing the “path” from a module’s global scope to a class, function or method defined in that module, as defined in PEP 3155. For top-level functions and classes, the qualified name is the same as the object’s name:

```python
>>> class C:
...     class D:
...         def meth(self):
...             pass
...
>>> C.__qualname__
'C'
>>> C.D.__qualname__
'C.D'
>>> C.D.meth.__qualname__
'C.D.meth'
```

When used to refer to modules, the fully qualified name means the entire dotted path to the module, including any parent packages, e.g. `email.mime.text`:

```python
>>> import email.mime.text
>>> email.mime.text.__name__
'email.mime.text'
```

**Reference count** The number of references to an object. When the reference count of an object drops to zero, it is deallocated. Reference counting is generally not visible to Python code, but it is a key element of the CPython implementation. The `sys` module defines a `getrefcount()` function that programmers can call to return the reference count for a particular object.

**Regular package** A traditional package, such as a directory containing an `__init__.py` file.

See also namespace package.

**__slots__** A declaration inside a class that saves memory by pre-declaring space for instance attributes and eliminating instance dictionaries. Though popular, the technique is somewhat tricky to get right and is best reserved for rare cases where there are large numbers of instances in a memory-critical application.

**Sequence** An iterable which supports efficient element access using integer indices via the `__getitem__()` special method and defines a `__len__()` method that returns the length of the sequence. Some built-in sequence types are `list`, `str`, `tuple`, and `bytes`. Note that `dict` also supports `__getitem__()` and `__len__()`, but is considered a mapping rather than a sequence because the lookups use arbitrary immutable keys rather than integers.

**Slice** An object usually containing a portion of a sequence. A slice is created using the subscript notation, `[ ]` with colons between numbers when several are given, such as in `variable_name[1:3:5]`. The bracket (subscript) notation uses `slice` objects internally.

**Special method** A method that is called implicitly by Python to execute a certain operation on a type, such as addition. Such methods have names starting and ending with doubles underscores. Special methods are documented in `specialnames`.

**Statement** A statement is part of a suite (a “block” of code). A statement is either an expression or one of several constructs with a keyword, such as `if`, `while` or `for`.

**Struct sequence** A tuple with named elements. Struct sequences expose an interface similar to `named tuple` in that elements can either be accessed either by index or as an attribute. However, they do not have
any of the named tuple methods like \_make() or \_asdict(). Examples of struct sequences include
\texttt{sys.float\_info} and the return value of \texttt{os.stat()}.

**triple-quoted string**  A string which is bound by three instances of either a quotation mark (") or an apostrophe ('). While they don’t provide any functionality not available with single-quoted strings, they are useful for a number of reasons. They allow you to include unescaped single and double quotes within a string and they can span multiple lines without the use of the continuation character, making them especially useful when writing docstrings.

**type**  The type of a Python object determines what kind of object it is; every object has a type. An object’s type is accessible as its \_\texttt{class} attribute or can be retrieved with \texttt{type(obj)}.

**universal newlines**  A manner of interpreting text streams in which all of the following are recognized as ending a line: the Unix end-of-line convention ‘\n’, the Windows convention ‘\r\n’, and the old Macintosh convention ‘\r’. See \texttt{PEP 278} and \texttt{PEP 3116}, as well as \texttt{str.splitlines()} for an additional use.

**view**  The objects returned from \texttt{dict.keys()}, \texttt{dict.values()}, and \texttt{dict.items()} are called dictionary views. They are lazy sequences that will see changes in the underlying dictionary. To force the dictionary view to become a full list use \texttt{list(dictview)}. See \texttt{dict-views}.

**virtual machine**  A computer defined entirely in software. Python’s virtual machine executes the \texttt{bytecode} emitted by the bytecode compiler.

**Zen of Python**  Listing of Python design principles and philosophies that are helpful in understanding and using the language. The listing can be found by typing “\texttt{import this}” at the interactive prompt.
ABOUT THESE DOCUMENTS

These documents are generated from `reStructuredText` sources by `Sphinx`, a document processor specifically written for the Python documentation.

Development of the documentation and its toolchain takes place on the `docs@python.org` mailing list. We’re always looking for volunteers wanting to help with the docs, so feel free to send a mail there!

Many thanks go to:

- Fred L. Drake, Jr., the creator of the original Python documentation toolset and writer of much of the content;
- the `Docutils` project for creating `reStructuredText` and the `Docutils` suite;
- Fredrik Lundh for his `Alternative Python Reference` project from which Sphinx got many good ideas.

See `reporting-bugs` for information how to report bugs in this documentation, or Python itself.

### B.1 Contributors to the Python Documentation

Many people have contributed to the Python language, the Python standard library, and the Python documentation. See `Misc/ACKS` in the Python source distribution for a partial list of contributors.

It is only with the input and contributions of the Python community that Python has such wonderful documentation – Thank You!
HISTORY AND LICENSE

C.1 History of the software

Python was created in the early 1990s by Guido van Rossum at Stichting Mathematisch Centrum (CWI, see http://www.cwi.nl/) in the Netherlands as a successor of a language called ABC. Guido remains Python’s principal author, although it includes many contributions from others.

In 1995, Guido continued his work on Python at the Corporation for National Research Initiatives (CNRI, see http://www.cnri.reston.va.us/) in Reston, Virginia where he released several versions of the software.

In May 2000, Guido and the Python core development team moved to BeOpen.com to form the BeOpen Python-Labs team. In October of the same year, the PythonLabs team moved to Digital Creations (now Zope Corporation; see http://www.zope.com/). In 2001, the Python Software Foundation (PSF, see http://www.python.org/psf/) was formed, a non-profit organization created specifically to own Python-related Intellectual Property. Zope Corporation is a sponsoring member of the PSF.

All Python releases are Open Source (see http://www.opensource.org/ for the Open Source Definition). Historically, most, but not all, Python releases have also been GPL-compatible; the table below summarizes the various releases.

<table>

Note: GPL-compatible doesn’t mean that we’re distributing Python under the GPL. All Python licenses, unlike the GPL, let you distribute a modified version without making your changes open source. The GPL-compatible licenses make it possible to combine Python with other software that is released under the GPL; the others don’t.

Thanks to the many outside volunteers who have worked under Guido’s direction to make these releases possible.

C.2 Terms and conditions for accessing or otherwise using Python

PSF LICENSE AGREEMENT FOR PYTHON 3.3.3
Distributing Python Modules, Release 3.3.3

1. This LICENSE AGREEMENT is between the Python Software Foundation (“PSF”), and the Individual or Organization (“Licensee”) accessing and otherwise using Python 3.3.3 software in source or binary form and its associated documentation.

2. Subject to the terms and conditions of this License Agreement, PSF hereby grants Licensee a nonexclusive, royalty-free, world-wide license to reproduce, analyze, test, perform and/or display publicly, prepare derivative works, distribute, and otherwise use Python 3.3.3 alone or in any derivative version, provided, however, that PSF’s License Agreement and PSF’s notice of copyright, i.e., “Copyright © 2001-2013 Python Software Foundation; All Rights Reserved” are retained in Python 3.3.3 alone or in any derivative version prepared by Licensee.

3. In the event Licensee prepares a derivative work that is based on or incorporates Python 3.3.3 or any part thereof, and wants to make the derivative work available to others as provided herein, then Licensee hereby agrees to include in any such work a brief summary of the changes made to Python 3.3.3.

4. PSF is making Python 3.3.3 available to Licensee on an “AS IS” basis. PSF MAKES NO REPRESENTATIONS OR WARRANTIES, EXPRESS OR IMPLIED. BY WAY OF EXAMPLE, BUT NOT LIMITATION, PSF MAKES NO AND DISCLAIMS ANY REPRESENTATION OR WARRANTY OF MERCHANTABILITY OR FITNESS FOR ANY PARTICULAR PURPOSE OR THAT THE USE OF PYTHON 3.3.3 WILL NOT INFRINGE ANY THIRD PARTY RIGHTS.

5. PSF SHALL NOT BE LIABLE TO LICENSEE OR ANY OTHER USERS OF PYTHON 3.3.3 FOR ANY INCIDENTAL, SPECIAL, OR CONSEQUENTIAL DAMAGES OR LOSS AS A RESULT OF MODIFYING, DISTRIBUTING, OR OTHERWISE USING PYTHON 3.3.3, OR ANY DERIVATIVE THEREOF, EVEN IF ADVISED OF THE POSSIBILITY THEREOF.

6. This License Agreement will automatically terminate upon a material breach of its terms and conditions.

7. Nothing in this License Agreement shall be deemed to create any relationship of agency, partnership, or joint venture between PSF and Licensee. This License Agreement does not grant permission to use PSF trademarks or trade name in a trademark sense to endorse or promote products or services of Licensee, or any third party.

8. By copying, installing or otherwise using Python 3.3.3, Licensee agrees to be bound by the terms and conditions of this License Agreement.

BEOPEN.COM LICENSE AGREEMENT FOR PYTHON 2.0

BEOPEN PYTHON OPEN SOURCE LICENSE AGREEMENT VERSION 1

1. This LICENSE AGREEMENT is between BeOpen.com (“BeOpen”), having an office at 160 Saratoga Avenue, Santa Clara, CA 95051, and the Individual or Organization (“Licensee”) accessing and otherwise using this software in source or binary form and its associated documentation (“the Software”).

2. Subject to the terms and conditions of this BeOpen Python License Agreement, BeOpen hereby grants Licensee a non-exclusive, royalty-free, world-wide license to reproduce, analyze, test, perform and/or display publicly, prepare derivative works, distribute, and otherwise use the Software alone or in any derivative version, provided, however, that the BeOpen Python License is retained in the Software, alone or in any derivative version prepared by Licensee.

3. BeOpen is making the Software available to Licensee on an “AS IS” basis. BEOPEN MAKES NO REPRESENTATIONS OR WARRANTIES, EXPRESS OR IMPLIED. BY WAY OF EXAMPLE, BUT NOT LIMITATION, BEOPEN MAKES NO AND DISCLAIMS ANY REPRESENTATION OR WARRANTY OF MERCHANTABILITY OR FITNESS FOR ANY PARTICULAR PURPOSE OR THAT THE USE OF THE SOFTWARE WILL NOT INFRINGE ANY THIRD PARTY RIGHTS.

4. BEOPEN SHALL NOT BE LIABLE TO LICENSEE OR ANY OTHER USERS OF THE SOFTWARE FOR ANY INCIDENTAL, SPECIAL, OR CONSEQUENTIAL DAMAGES OR LOSS AS A RESULT OF USING, MODIFYING OR DISTRIBUTING THE SOFTWARE, OR ANY DERIVATIVE THEREOF, EVEN IF ADVISED OF THE POSSIBILITY THEREOF.

5. This License Agreement will automatically terminate upon a material breach of its terms and conditions.

6. This License Agreement shall be governed by and interpreted in all respects by the law of the State of California, excluding conflict of law provisions. Nothing in this License Agreement shall be deemed to create any relationship of agency, partnership, or joint venture between BeOpen and Licensee. This License
Agreement does not grant permission to use BeOpen trademarks or trade names in a trademark sense to endorse or promote products or services of Licensee, or any third party. As an exception, the “BeOpen Python” logos available at http://www.pythonlabs.com/logos.html may be used according to the permissions granted on that web page.

7. By copying, installing or otherwise using the software, Licensee agrees to be bound by the terms and conditions of this License Agreement.

CNRI LICENSE AGREEMENT FOR PYTHON 1.6.1

1. This LICENSE AGREEMENT is between the Corporation for National Research Initiatives, having an office at 1895 Preston White Drive, Reston, VA 20191 (“CNRI”), and the Individual or Organization (“Licensee”) accessing and otherwise using Python 1.6.1 software in source or binary form and its associated documentation.

2. Subject to the terms and conditions of this License Agreement, CNRI hereby grants Licensee a nonexclusive, royalty-free, world-wide license to reproduce, analyze, test, perform and/or display publicly, prepare derivative works, distribute, and otherwise use Python 1.6.1 alone or in any derivative version, provided, however, that CNRI’s License Agreement and CNRI’s notice of copyright, i.e., “Copyright © 1995-2001 Corporation for National Research Initiatives; All Rights Reserved” are retained in Python 1.6.1 alone or in any derivative version prepared by Licensee. Alternately, in lieu of CNRI’s License Agreement, Licensee may substitute the following text (omitting the quotes): “Python 1.6.1 is made available subject to the terms and conditions in CNRI’s License Agreement. This Agreement together with Python 1.6.1 may be located on the Internet using the following unique, persistent identifier (known as a handle): 1895.22/1013. This Agreement may also be obtained from a proxy server on the Internet using the following URL: http://hdl.handle.net/1895.22/1013.”

3. In the event Licensee prepares a derivative work that is based on or incorporates Python 1.6.1 or any part thereof, and wants to make the derivative work available to others as provided herein, then Licensee hereby agrees to include in any such work a brief summary of the changes made to Python 1.6.1.

4. CNRI is making Python 1.6.1 available to Licensee on an “AS IS” basis. CNRI MAKES NO REPRESENTATIONS OR WARRANTIES, EXPRESS OR IMPLIED. BY WAY OF EXAMPLE, BUT NOT LIMITATION, CNRI MAKES NO AND DISCLAIMS ANY REPRESENTATION OR WARRANTY OF MERCHANTABILITY OR FITNESS FOR ANY PARTICULAR PURPOSE OR THAT THE USE OF PYTHON 1.6.1 WILL NOT INFRINGE ANY THIRD PARTY RIGHTS.

5. CNRI SHALL NOT BE LIABLE TO LICENSEE OR ANY OTHER USERS OF PYTHON 1.6.1 FOR ANY INCIDENTAL, SPECIAL, OR CONSEQUENTIAL DAMAGES OR LOSS AS A RESULT OF MODIFYING, DISTRIBUTING, OR OTHERWISE USING PYTHON 1.6.1, OR ANY DERIVATIVE THEREOF, EVEN IF ADVISED OF THE POSSIBILITY THEREOF.

6. This License Agreement will automatically terminate upon a material breach of its terms and conditions.

7. This License Agreement shall be governed by the federal intellectual property law of the United States, including without limitation the federal copyright law, and, to the extent such U.S. federal law does not apply, by the law of the Commonwealth of Virginia, excluding Virginia’s conflict of law provisions. Notwithstanding the foregoing, with regard to derivative works based on Python 1.6.1 that incorporate non-separable material that was previously distributed under the GNU General Public License (GPL), the law of the Commonwealth of Virginia shall govern this License Agreement only as to issues arising under or with respect to Paragraphs 4, 5, and 7 of this License Agreement. Nothing in this License Agreement shall be deemed to create any relationship of agency, partnership, or joint venture between CNRI and Licensee. This License Agreement does not grant permission to use CNRI trademarks or trade name in a trademark sense to endorse or promote products or services of Licensee, or any third party.

8. By clicking on the “ACCEPT” button where indicated, or by copying, installing or otherwise using Python 1.6.1, Licensee agrees to be bound by the terms and conditions of this License Agreement.

ACCEPT

CWI LICENSE AGREEMENT FOR PYTHON 0.9.0 THROUGH 1.2

Copyright © 1991 - 1995, Stichting Mathematisch Centrum Amsterdam, The Netherlands. All rights reserved.
Permission to use, copy, modify, and distribute this software and its documentation for any purpose and without fee is hereby granted, provided that the above copyright notice appear in all copies and that both that copyright notice and this permission notice appear in supporting documentation, and that the name of Stichting Mathematisch Centrum or CWI not be used in advertising or publicity pertaining to distribution of the software without specific, written prior permission.

STICHTING MATHEMATISCH CENTRUM DISCLAIMS ALL WARRANTIES WITH REGARD TO THIS SOFTWARE, INCLUDING ALL IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS. IN NO EVENT SHALL STICHTING MATHEMATISCH CENTRUM BE LIABLE FOR ANY SPECIAL, INDIRECT OR CONSEQUENTIAL DAMAGES OR ANY DAMAGES WHATSOEVER RESULTING FROM LOSS OF USE, DATA OR PROFITS, WHETHER IN AN ACTION OF CONTRACT, NEGLIGENCE OR OTHER TORTIOUS ACTION, ARISING OUT OF OR IN CONNECTION WITH THE USE OR PERFORMANCE OF THIS SOFTWARE.

C.3 Licenses and Acknowledgements for Incorporated Software

This section is an incomplete, but growing list of licenses and acknowledgements for third-party software incorporated in the Python distribution.

C.3.1 Mersenne Twister

The _random module includes code based on a download from http://www.math.sci.hiroshima-u.ac.jp/~m-mat/MT/MT2002/emt19937ar.html. The following are the verbatim comments from the original code:

A C-program for MT19937, with initialization improved 2002/1/26.
Coded by Takuji Nishimura and Makoto Matsumoto.

Before using, initialize the state by using init_genrand(seed)
or init_by_array(init_key, key_length).

Copyright (C) 1997 - 2002, Makoto Matsumoto and Takuji Nishimura,
All rights reserved.

Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met:

1. Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer.

2. Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution.

3. The names of its contributors may not be used to endorse or promote products derived from this software without specific prior written permission.

THIS SOFTWARE IS PROVIDED BY THE COPYRIGHT HOLDERS AND CONTRIBUTORS "AS IS" AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE COPYRIGHT OWNER OR CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING
NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

Any feedback is very welcome.
http://www.math.sci.hiroshima-u.ac.jp/~m-mat/MT/emt.html
email: m-mat @ math.sci.hiroshima-u.ac.jp (remove space)

C.3.2 Sockets

The socket module uses the functions, getaddrinfo(), and getnameinfo(), which are coded in separate source files from the WIDE Project, http://www.wide.ad.jp/.

All rights reserved.

Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met:
1. Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer.
2. Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution.
3. Neither the name of the project nor the names of its contributors may be used to endorse or promote products derived from this software without specific prior written permission.

THIS SOFTWARE IS PROVIDED BY THE PROJECT AND CONTRIBUTORS ‘‘AS IS’’ AND GAI ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE PROJECT OR CONTRIBUTORS BE LIABLE FOR GAI ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON GAI ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN GAI ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

C.3.3 Floating point exception control

The source for the fpectl module includes the following notice:

```
/ Copyright (c) 1996. \       
| The Regents of the University of California. | 
| All rights reserved. | 
| Permission to use, copy, modify, and distribute this software for any purpose without fee is hereby granted, provided that this entire notice is included in all copies of any software which is or includes a copy or modification of this software and in all copies of the supporting documentation for such software. | 
| This work was produced at the University of California, Lawrence Livermore National Laboratory under contract no. W-7405-ENG-48 | 
```
C.3.4 Asynchronous socket services

The `asynchat` and `asyncore` modules contain the following notice:

Copyright 1996 by Sam Rushing

All Rights Reserved

Permission to use, copy, modify, and distribute this software and its documentation for any purpose and without fee is hereby granted, provided that the above copyright notice appear in all copies and that both that copyright notice and this permission notice appear in supporting documentation, and that the name of Sam Rushing not be used in advertising or publicity pertaining to distribution of the software without specific, written prior permission.

SAM RUSHING DISCLAIMS ALL WARRANTIES WITH REGARD TO THIS SOFTWARE, INCLUDING ALL IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS, IN NO EVENT SHALL SAM RUSHING BE LIABLE FOR ANY SPECIAL, INDIRECT OR CONSEQUENTIAL DAMAGES OR ANY DAMAGES WHATSOEVER RESULTING FROM LOSS OF USE, DATA OR PROFITS, WHETHER IN AN ACTION OF CONTRACT, NEGLIGENCE OR OTHER TORTIOUS ACTION, ARISING OUT OF OR IN CONNECTION WITH THE USE OR PERFORMANCE OF THIS SOFTWARE.

C.3.5 Cookie management

The `http.cookies` module contains the following notice:

Copyright 2000 by Timothy O’Malley <timo@alum.mit.edu>

All Rights Reserved

Permission to use, copy, modify, and distribute this software
and its documentation for any purpose and without fee is hereby
granted, provided that the above copyright notice appear in all
copies and that both that copyright notice and this permission
notice appear in supporting documentation, and that the name of
Timothy O'Malley not be used in advertising or publicity
pertaining to distribution of the software without specific, written
prior permission.

Timothy O'Malley DISCLAIMS ALL WARRANTIES WITH REGARD TO THIS
SOFTWARE, INCLUDING ALL IMPLIED WARRANTIES OF MERCHANTABILITY
AND FITNESS, IN NO EVENT SHALL Timothy O'Malley BE LIABLE FOR
ANY SPECIAL, INDIRECT OR CONSEQUENTIAL DAMAGES OR ANY DAMAGES
WHATSOEVER RESULTING FROM LOSS OF USE, DATA OR PROFITS,
WHETHER IN AN ACTION OF CONTRACT, NEGLIGENCE OR OTHER TORTIOUS
ACTION, ARISING OUT OF OR IN CONNECTION WITH THE USE OR
PERFORMANCE OF THIS SOFTWARE.

C.3.6 Execution tracing

The trace module contains the following notice:

portions copyright 2001, Autonomous Zones Industries, Inc., all rights...
err... reserved and offered to the public under the terms of the
Python 2.2 license.
Author: Zooko O'Whielacronx
http://zooko.com/
mailto:zooko@zooko.com

Copyright 2000, Mojam Media, Inc., all rights reserved.
Author: Skip Montanaro

Copyright 1999, Bioreason, Inc., all rights reserved.
Author: Andrew Dalke

Copyright 1995-1997, Automatrix, Inc., all rights reserved.
Author: Skip Montanaro

Copyright 1991-1995, Stichting Mathematisch Centrum, all rights reserved.

Permission to use, copy, modify, and distribute this Python software and
its associated documentation for any purpose without fee is hereby
granted, provided that the above copyright notice appears in all copies,
and that both that copyright notice and this permission notice appear in
supporting documentation, and that the name of neither Automatrix,
Bioreason or Mojam Media be used in advertising or publicity pertaining to
distribution of the software without specific, written prior permission.

C.3.7 UUencode and UUdecode functions

The uu module contains the following notice:

Copyright 1994 by Lance Ellinghouse
Cathedral City, California Republic, United States of America.
All Rights Reserved
Permission to use, copy, modify, and distribute this software and its
documentation for any purpose and without fee is hereby granted,
Distributing Python Modules, Release 3.3.3

provided that the above copyright notice appear in all copies and that
both that copyright notice and this permission notice appear in
supporting documentation, and that the name of Lance Ellinghouse
not be used in advertising or publicity pertaining to distribution
of the software without specific, written prior permission.
LANE ELLINGHOUSE DISCLAIMS ALL WARRANTIES WITH REGARD TO
THIS SOFTWARE, INCLUDING ALL IMPLIED WARRANTIES OF MERCHANTABILITY AND
FITNESS, IN NO EVENT SHALL LANCE ELLINGHOUSE CENTRUM BE LIABLE
FOR ANY SPECIAL, INDIRECT OR CONSEQUENTIAL DAMAGES OR ANY DAMAGES
WHATSOEVER RESULTING FROM LOSS OF USE, DATA OR PROFITS, WHETHER IN AN
ACTION OF CONTRACT, NEGLIGENCE OR OTHER TORTIOUS ACTION, ARISING OUT
OF OR IN CONNECTION WITH THE USE OR PERFORMANCE OF THIS SOFTWARE.

Modified by Jack Jansen, CWI, July 1995:
- Use binascii module to do the actual line-by-line conversion
  between ascii and binary. This results in a 1000-fold speedup. The C
  version is still 5 times faster, though.
- Arguments more compliant with Python standard

C.3.8 XML Remote Procedure Calls

The xmlrpc.client module contains the following notice:

The XML-RPC client interface is

Copyright (c) 1999-2002 by Secret Labs AB
Copyright (c) 1999-2002 by Fredrik Lundh

By obtaining, using, and/or copying this software and/or its
associated documentation, you agree that you have read, understood,
and will comply with the following terms and conditions:

Permission to use, copy, modify, and distribute this software and
its associated documentation for any purpose and without fee is
hereby granted, provided that the above copyright notice appears in
all copies, and that both that copyright notice and this permission
notice appear in supporting documentation, and that the name of
Secret Labs AB or the author not be used in advertising or publicity
pertaining to distribution of the software without specific, written
prior permission.

SECRET LABS AB AND THE AUTHOR DISCLAIMS ALL WARRANTIES WITH REGARD
TO THIS SOFTWARE, INCLUDING ALL IMPLIED WARRANTIES OF MERCHANT-
ABILITY AND FITNESS. IN NO EVENT SHALL SECRET LABS AB OR THE AUTHOR
BE LIABLE FOR ANY SPECIAL, INDIRECT OR CONSEQUENTIAL DAMAGES OR ANY
DAMAGES WHATSOEVER RESULTING FROM LOSS OF USE, DATA OR PROFITS,
WHETHER IN AN ACTION OF CONTRACT, NEGLIGENCE OR OTHER TORTIOUS
ACTION, ARISING OUT OF OR IN CONNECTION WITH THE USE OR PERFORMANCE
OF THIS SOFTWARE.

C.3.9 test_epoll

The test_epoll contains the following notice:

Copyright (c) 2001-2006 Twisted Matrix Laboratories.

Permission is hereby granted, free of charge, to any person obtaining
a copy of this software and associated documentation files (the "Software"), to deal in the Software without restriction, including without limitation the rights to use, copy, modify, merge, publish, distribute, sublicense, and/or sell copies of the Software, and to permit persons to whom the Software is furnished to do so, subject to the following conditions:

The above copyright notice and this permission notice shall be included in all copies or substantial portions of the Software.

THE SOFTWARE IS PROVIDED "AS IS", WITHOUT WARRANTY OF ANY KIND, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NONINFRINGEMENT. IN NO EVENT SHALL THE AUTHORS OR COPYRIGHT HOLDERS BE LIABLE FOR ANY CLAIM, DAMAGES OR OTHER LIABILITY, WHETHER IN AN ACTION OF CONTRACT, TORT OR OTHERWISE, ARISING FROM, OUT OF OR IN CONNECTION WITH THE SOFTWARE OR THE USE OR OTHER DEALINGS IN THE SOFTWARE.

C.3.10 Select kqueue

The select and contains the following notice for the kqueue interface:

Copyright (c) 2000 Doug White, 2006 James Knight, 2007 Christian Heimes
All rights reserved.

Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met:
1. Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer.
2. Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution.

THIS SOFTWARE IS PROVIDED BY THE AUTHOR AND CONTRIBUTORS `AS IS` AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE AUTHOR OR CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

C.3.11 strtod and dtoa

The file Python/dtoa.c, which supplies C functions dtoa and strtod for conversion of C doubles to and from strings, is derived from the file of the same name by David M. Gay, currently available from http://www.netlib.org/fp/. The original file, as retrieved on March 16, 2009, contains the following copyright and licensing notice:

/*************************************************************/
/* * The author of this software is David M. Gay. *
*/

C.3. Licenses and Acknowledgements for Incorporated Software
C.3.12 OpenSSL

The modules hashlib, posix, ssl, and crypt use the OpenSSL library for added performance if made available by the operating system. Additionally, the Windows installers for Python include a copy of the OpenSSL libraries, so we include a copy of the OpenSSL license here:

**LICENSE ISSUES**

The OpenSSL toolkit stays under a dual license, i.e. both the conditions of the OpenSSL License and the original SSLeay license apply to the toolkit. See below for the actual license texts. Actually both licenses are BSD-style Open Source licenses. In case of any license issues related to OpenSSL please contact openssl-core@openssl.org.

**OpenSSL License**

/* ====================================================================
 * Copyright (c) 1998-2008 The OpenSSL Project. All rights reserved.
 *
 * Redistribution and use in source and binary forms, with or without
 * modification, are permitted provided that the following conditions
 * are met:
 * 1. Redistributions of source code must retain the above copyright
 *    notice, this list of conditions and the following disclaimer.
 * 2. Redistributions in binary form must reproduce the above copyright
 *    notice, this list of conditions and the following disclaimer in
 *    the documentation and/or other materials provided with the
 *    distribution.
 * 3. All other uses must be explicitly approved by the OpenSSL Project
 *    Development Team (http://www.openssl.org/).
 * 4. The above copyright and this permission notice applies to
 *    linked/fused combinations of this library with other libraries.
 * 5. By modifying the OpenSSL library or creating a derivative work,
 *    users acknowledge that they have modified the OpenSSL library,
 *    thereby making them contributors to the OpenSSL project.
 *    Users agree to contribute any modifications they make back to the
 *    OpenSSL project.
 * ====================================================================
 */
5. Products derived from this software may not be called "OpenSSL"
   nor may "OpenSSL" appear in their names without prior written
   permission of the OpenSSL Project.

6. Redistributions of any form whatsoever must retain the following
   acknowledgment:
   "This product includes software developed by the OpenSSL Project
   for use in the OpenSSL Toolkit (http://www.openssl.org/)

THIS SOFTWARE IS PROVIDED BY THE OpenSSL PROJECT ''AS IS'' AND ANY
EXRESSED OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE
IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR

OF THE POSSIBILITY OF SUCH DAMAGE.

Original SSLeay License
-----------------------
/* Copyright (C) 1995-1998 Eric Young (eay@cryptsoft.com)
   All rights reserved.

   This package is an SSL implementation written
   by Eric Young (eay@cryptsoft.com).
   The implementation was written so as to conform with Netscapes SSL.

   This library is free for commercial and non-commercial use as long as
   the following conditions are aheared to. The following conditions
   apply to all code found in this distribution, be it the RC4, RSA,
   lhash, DES, etc., code; not just the SSL code. The SSL documentation
   included with this distribution is covered by the same copyright terms
   except that the holder is Tim Hudson (tjh@cryptsoft.com).

   Copyright remains Eric Young’s, and as such any Copyright notices in
   the code are not to be removed.
   If this package is used in a product, Eric Young should be given attribution
   as the author of the parts of the library used.
   This can be in the form of a textual message at program startup or
   in documentation (online or textual) provided with the package.

   Redistribution and use in source and binary forms, with or without
   modification, are permitted provided that the following conditions
   are met:
   1. Redistributions of source code must retain the copyright
      notice, this list of conditions and the following disclaimer.
* 2. Redistributions in binary form must reproduce the above copyright
   notice, this list of conditions and the following disclaimer in the
   documentation and/or other materials provided with the distribution.
* 3. All advertising materials mentioning features or use of this software
   must display the following acknowledgement:
   "This product includes cryptographic software written by
   Eric Young (eay@cryptsoft.com)"
   The word ‘cryptographic’ can be left out if the rouines from the library
   being used are not cryptographic related :-).
* 4. If you include any Windows specific code (or a derivative thereof) from
   the apps directory (application code) you must include an acknowledgement:
   "This product includes software written by Tim Hudson (tjh@cryptsoft.com)"

   THIS SOFTWARE IS PROVIDED BY ERIC YOUNG ‘AS IS’ AND
   ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE
   IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE
   ARE DISCLAIMED. IN NO EVENT SHALL THE AUTHOR OR CONTRIBUTORS BE LIABLE
   FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL
   DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS
   OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION)
   HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT
   LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY
   OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF
   SUCH DAMAGE.

   The licence and distribution terms for any publically available version or
   derivative of this code cannot be changed. i.e. this code cannot simply be
   copied and put under another distribution licence
   [including the GNU Public Licence.]
*/

C.3.13 expat

The pyexpat extension is built using an included copy of the expat sources unless the build is configured
--with-system-expat:

Copyright (c) 1998, 1999, 2000 Thai Open Source Software Center Ltd
and Clark Cooper

Permission is hereby granted, free of charge, to any person obtaining
a copy of this software and associated documentation files (the
"Software"), to deal in the Software without restriction, including
without limitation the rights to use, copy, modify, merge, publish,
distribute, sublicense, and/or sell copies of the Software, and to
permit persons to whom the Software is furnished to do so, subject to
the following conditions:

The above copyright notice and this permission notice shall be included
in all copies or substantial portions of the Software.

THE SOFTWARE IS PROVIDED "AS IS", WITHOUT WARRANTY OF ANY KIND,
EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE WARRANTIES OF
MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NONINFRINGEMENT.
IN NO EVENT SHALL THE AUTHORS OR COPYRIGHT HOLDERS BE LIABLE FOR ANY
CLAIM, DAMAGES OR OTHER LIABILITY, WHETHER IN AN ACTION OF CONTRACT,
TORT OR OTHERWISE, ARISING FROM, OUT OF OR IN CONNECTION WITH THE
SOFTWARE OR THE USE OR OTHER DEALINGS IN THE SOFTWARE.
C.3.14 libffi

The _ctypes extension is built using an included copy of the libffi sources unless the build is configured --with-system-libffi:

Copyright (c) 1996-2008 Red Hat, Inc and others.

Permission is hereby granted, free of charge, to any person obtaining a copy of this software and associated documentation files (the ``Software''), to deal in the Software without restriction, including without limitation the rights to use, copy, modify, merge, publish, distribute, sublicense, and/or sell copies of the Software, and to permit persons to whom the Software is furnished to do so, subject to the following conditions:

The above copyright notice and this permission notice shall be included in all copies or substantial portions of the Software.

THE SOFTWARE IS PROVIDED ``AS IS'', WITHOUT WARRANTY OF ANY KIND, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NONINFRINGEMENT. IN NO EVENT SHALL THE AUTHORS OR COPYRIGHT HOLDERS BE LIABLE FOR ANY CLAIM, DAMAGES OR OTHER LIABILITY, WHETHER IN AN ACTION OF CONTRACT, TORT OR OTHERWISE, ARISING FROM, OUT OF OR IN CONNECTION WITH THE SOFTWARE OR THE USE OR OTHER DEALINGS IN THE SOFTWARE.

C.3.15 zlib

The zlib extension is built using an included copy of the zlib sources if the zlib version found on the system is too old to be used for the build:

Copyright (C) 1995-2011 Jean-loup Gailly and Mark Adler

This software is provided `as-is', without any express or implied warranty. In no event will the authors be held liable for any damages arising from the use of this software.

Permission is granted to anyone to use this software for any purpose, including commercial applications, and to alter it and redistribute it freely, subject to the following restrictions:

1. The origin of this software must not be misrepresented; you must not claim that you wrote the original software. If you use this software in a product, an acknowledgment in the product documentation would be appreciated but is not required.

2. Altered source versions must be plainly marked as such, and must not be misrepresented as being the original software.
